1. Introduction: The Origins and Background of SP(P)S

The main advantage of solid phase synthesis (SPS) in comparison to classical solution phase synthesis is the fast and easy separation of desired product and excess reagents by filtration. In the most common form of solid phase synthesis, the molecule being synthesized (e.g. a growing peptide chain) is attached to an insoluble solid support that is swollen in a certain solvent, while reagents are added to the suspension in a dissolved state. This setup enables the removal of excess reagent and dissolved byproducts by simply discarding the reaction solution by filtration followed by washing of the resin with various solvents. Consequently, an excess of reagents can usually be employed in SPS in order to shorten reaction times and ideally allow for a quantitative turnover of the substrate, which in turn leads to higher yields.

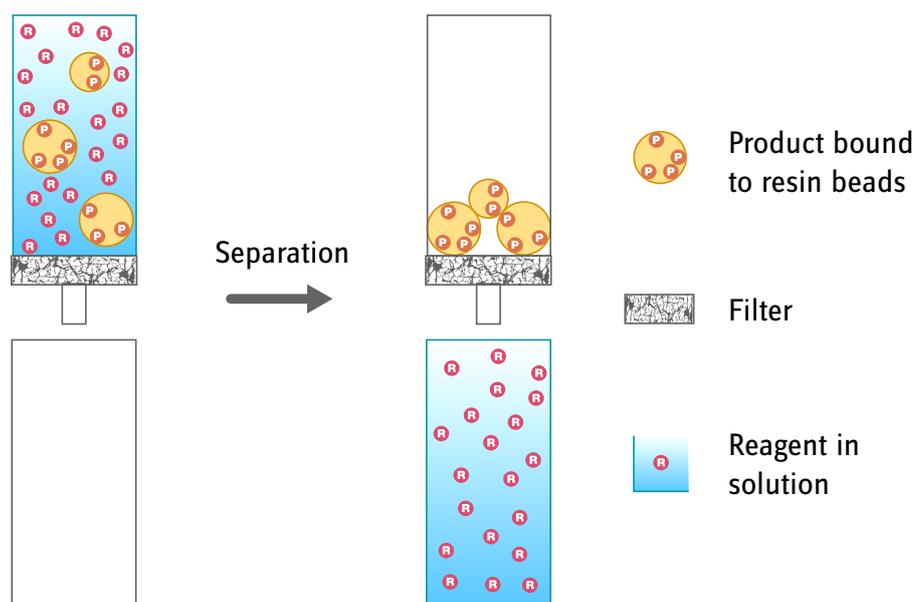

Fig. 1: Solid-supported synthesis enables fast and easy separation of product and reactants as one of them is bound to insoluble resin beads that can be simply filtered off from the reaction solution.

The main advantages of SPS are:

1. Fast work-up through easy separation of solid support from dissolved reactants and byproducts by filtration, and multiple, rapid washing steps.
2. Improved reaction times, turnover and yield by use of excess amounts of reagents.
3. The syntheses can easily be automatized.
4. Toxic or hazardous materials can be handled safely while they are attached to the resin.
5. Minimal physical product loss.
6. Pseudo-dilution phenomena on an individual bead can enable cyclization and avoid formation of dimers.

Originally SPS was developed to overcome the tedious and repetitive way of solution phase synthesis of peptides. Since that time it has been adapted and optimized for the synthesis and production of other biopolymers like DNA and RNA, as well as small organic molecules.

A typical solid phase synthesis consists of a series of alternating reaction and washing steps, the repetitiveness of which lends itself well to the (automated) synthesis of oligomeric structures such as oligonucleic acids, or peptides. The first reaction step in any solid phase peptide synthesis is the attachment of a bi- or more-functional amino acid to the solid support. Only one of the building blocks' functional groups is free to react, while all others are protected to avoid unwanted side-reactions. Subsequently, a second functionality is deprotected, so that a further amino acid can be coupled to the first resin-bound building block. The peptide chain is then elongated by reiterating this sequence of coupling and deprotection cycles. In the final steps, the molecule is cleaved from the resin, and all remaining protection groups are removed. This general reaction scheme is exemplified in Figure 2.

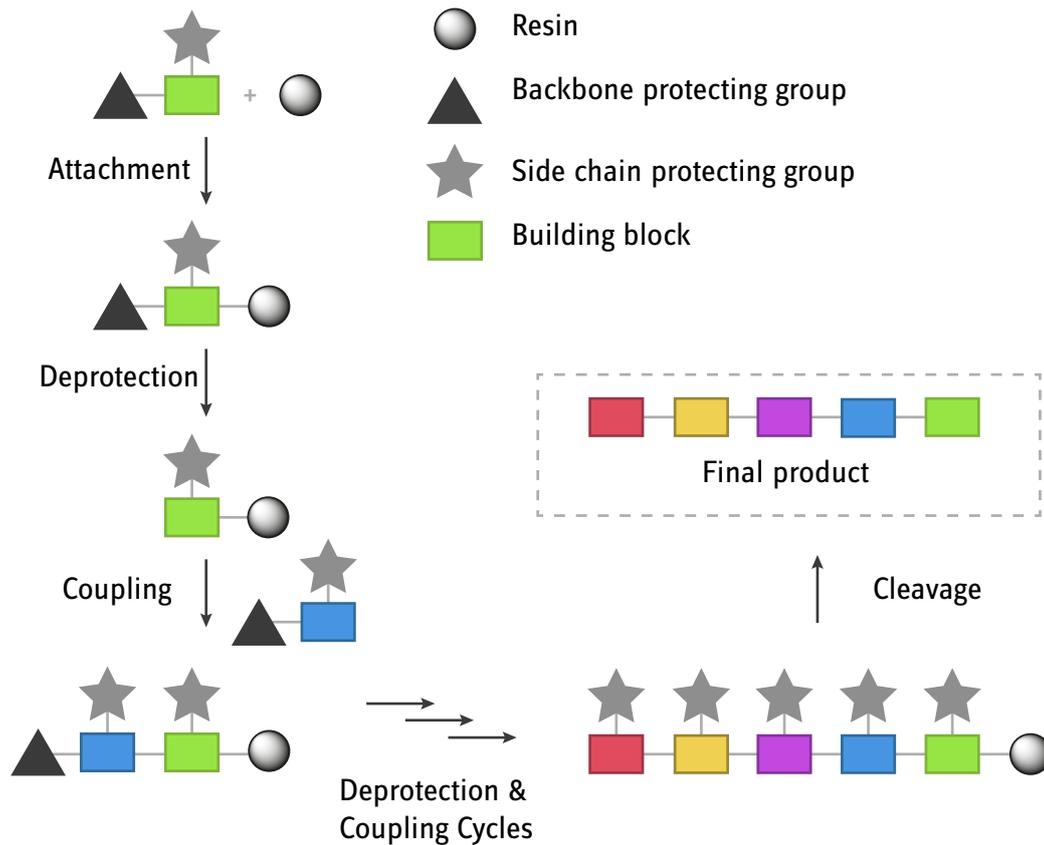

Fig. 2: General reaction sequence of SPS. After attachment of the first building block to the resin additional building blocks are attached in reaction cycles of deprotection and coupling and the final product is cleaved from the resin.

The downsides of SPS are the high solvent consumption as well as the difficult analysis of intermediates and target molecule between reaction steps as well as process control. Intermediates are bound to the resin, which makes direct analytics difficult or impossible.

1.1 How Solid Phase Chemical Synthesis Started

In the late 1950s and early 1960s, Robert Bruce Merrifield developed solid phase peptide synthesis (SPPS) and demonstrated its usefulness by synthesizing a tetrapeptide [1]. For this pioneering work and his ensuing research on SPPS, he was awarded the Nobel prize in 1984. The original resin named after him is a chloromethylated copolymer of styrene and divinylbenzene, which he chose over cellulose, polyvinyl alcohol, polymethacrylate and sulfonated polystyrene. This original discovery has survived until today, as most resins are still based on a polystyrene core. Depending on the exact polymerization conditions, the physical properties and morphology of the resin may vary. Especially for large scale syntheses, batch to batch variations of resins have to be monitored closely to ensure a consistent quality [2].

In parallel to the polystyrene solid support, Merrifield developed the Boc protection strategy for synthesizing peptides. In this strategy, the growing peptide chain is attached to the solid support via its C-terminus, while the N-terminus is protected with a Boc group (Figure 3).

1.2 Modern Synthetic and Strategic Developments of SPPS

Today, modern SPPS is performed using the Fmoc strategy due to the milder deprotection and cleavage conditions compared to the Boc-strategy. Being able to avoid the use of hazardous HF and to reduce the amount of TFA makes the Fmoc strategy more appealing. Moreover, the results for routine peptide syntheses are often superior for the Fmoc strategy [3]. A higher number of different Fmoc building blocks are available, enabling the synthesis of a larger diversity of peptides and/or allowing alternative synthetic strategies that are less laborious, faster and possibly more economic. In addition, the aromatic system of the dibenzofulvene and fulvene-piperidine adducts that are produced during the deprotection step allow the (automated) monitoring of the completeness of the Fmoc removal [4; 5]. Similar to the Boc strategy, the C-terminus is attached to the resin, while the N-terminus is protected using the base-labile Fmoc group (Figure 3).

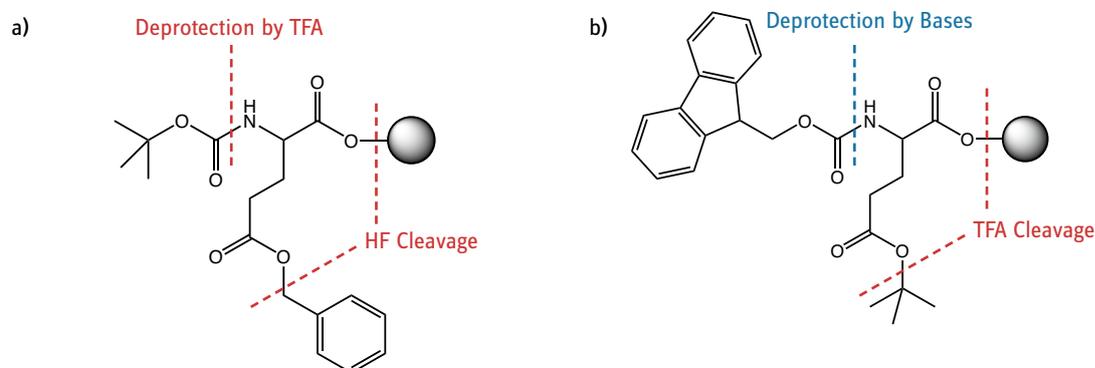

Fig. 3: Comparison of Boc-strategy a) and Fmoc-strategy b) for SPPS exemplified on a single, fully protected glutamic acid attached to the resin.

Apart from facilitating the synthesis of single structures, the ease of handling of the solid supported molecules has led to a variety of approaches to generate vast libraries of structures using combinatorial approaches. The split-mix technique splits a batch of resin into equal portions to which different molecules are coupled, and subsequently combines and mixes the resin beads [6]. By repeating these steps, extensive libraries of peptides and organic compounds can be generated as a mix within a short time and with relatively low effort. Alternatively the tea-bag method allows for the parallel synthesis of molecules not as a mixture, but as defined products, since the solid support is enclosed in a so-called teabag which serves as simple reaction vessel [7].

2. Physical Properties of Resins

2.1 Shape and Bead Size

The size of the resin beads can be described in different ways. The two most common are the standard US mesh size (also known as Tyler Mesh size) and the actual diameter of the resin beads. Both values are correlated to each other in an inverse manner as the density of the mesh of a sieve necessary to retrieve a certain particle size will get higher as the actual diameter of the resin beads gets smaller (Figure 4). The smaller the beads are, the faster the reaction kinetics will be, as surface area is larger in relation to the beads volume and allows fast diffusion of the reagents into the resin beads. However, if the beads are too small, the filtration time will be extended. For practical purposes a compromise between reaction kinetics and filtration time has to be made, so, a resin with a 100-200 mesh offers the best balance.

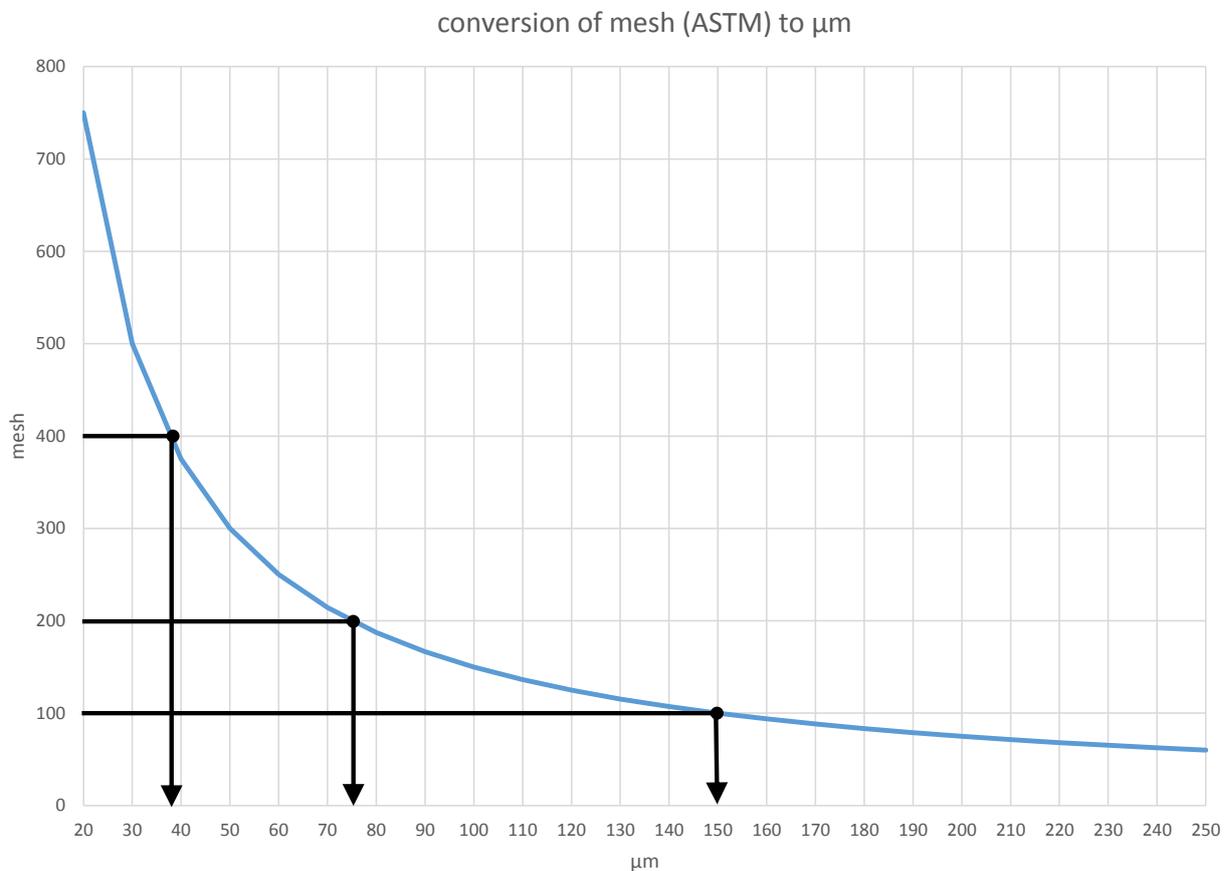

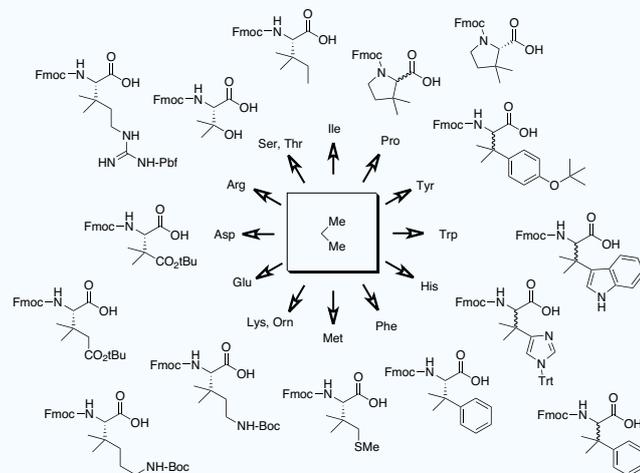

Fig. 4: Relation between mesh size and bead size of the particle [8]. The higher the mesh size is, the smaller are the resin beads.

size/ μm	beads/g	capacity/bead [nmol] (for Polystyrene, = 1 mmol/g)	capacity/bead [nmol] (for TentaGel® S, = 0.28 nmol/g)
750	4,620	232	65
700	5,010	196	55
650	6,260	157	44

5	1.54×10^{10}	6.4×10^{-5}	1.8×10^{-5}

Tab. 1: Correlation of particle size, number of beads per gram resin and capacity per single bead

P1'-Modification by β,β -Dimethyl Amino Acids Renders Peptide Therapeutics Resistant to Proteolytic Degradation

A new approach to improve proteolytic stability is the incorporation of β,β -dimethylated amino acids into peptide sequences at the P1' position (i.e. C-terminal of the enzyme cleavage site). This type of modification renders peptides highly resistant to serine protease degradation, usually without significant alteration of their biological activity. This includes stability towards dipeptidyl peptidase IV (DPP IV), dipeptidyl peptidase 8 (DPP8), fibroblast activation protein α (FAP α), α -lytic protease (α LP), trypsin, and chymotrypsin.

Inquire for the β,β -Dimethyl Amino Acids of your choice!

2.2 Cross-linkage and Swelling

The most common resins are based on polystyrene (PS). These resins can be further functionalized with spacers (e.g. PEG-based) in order to alter the swelling behavior in certain solvents, as well as to allow for different chemical strategies. Aside from polystyrene, other matrices are used as basis for resins in SPPS, including polyacrylate, polyethylene glycol, and polyacrylamide. By modifying a resin with a grafted spacer or by changing the nature of a core polymer, the properties of a solid support can be adjusted to a given solvent to allow for a high swelling. Good swelling properties are an important factor in the choice of solid support, since reaction kinetics in SPS are diffusion controlled, i.e. the reaction rates are higher the faster the reactants are able to diffuse into the resin. This holds especially true for the synthesis of large molecules, where a high swelling ensures sufficient space for the growing molecule, and thus minimizes aggregation. Otherwise, deprotection or coupling reactions may be hampered or even completely inhibited, leading to a low yield of the final product.

Polystyrene resins are prepared by radical polymerization. The three-dimensional resin network is established by crosslinking the linear polymer chains with divinylbenzene (DVB). (Figure 5).

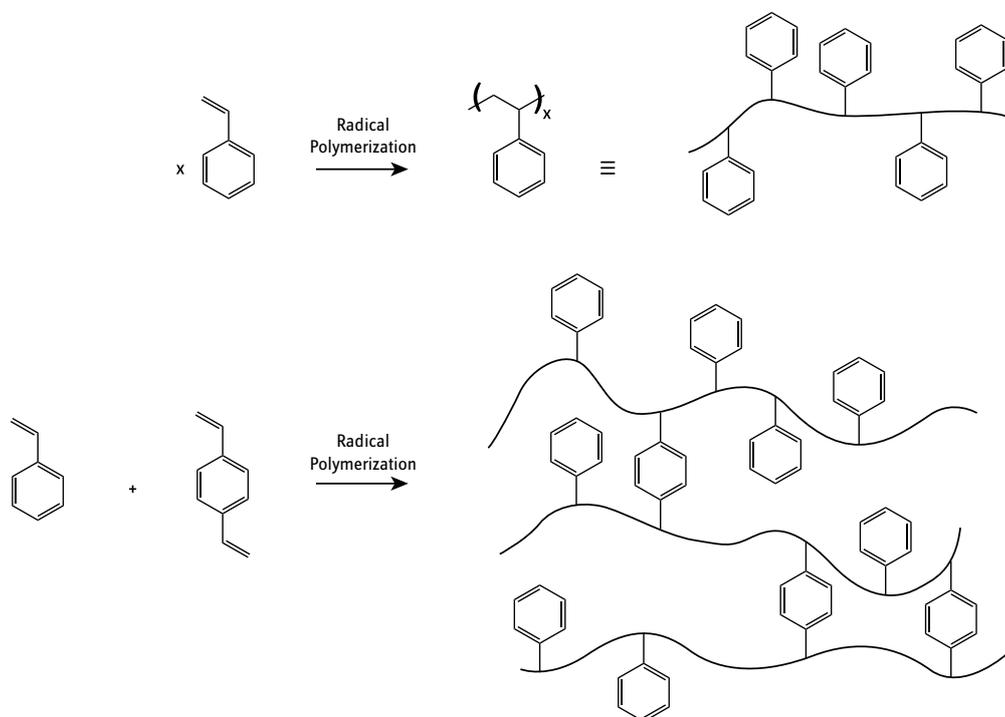

Fig. 5: A) Radical polymerization of styrene alone leads to single-stranded polystyrene chains.

B) A crosslinked network of these styrene chains is established by adding divinylbenzene to the reaction.

Polystyrene resins are typically crosslinked with 1% to 2% of DVB. In general, the higher the percentage of crosslinker, the lower the swelling of the corresponding resin in a given solvent (Figure 6). By attaching spacers to the polystyrene core, the properties of the PS-based solid support can be altered, a fact that can be used to tailor the resin's swelling properties to be compatible with certain solvents. For example, by grafting PEGspacers to the polystyrene core, even water can be used as solvent to swell the resin sufficiently, as exemplified by TentaGel resin that exhibits good swelling in both aqueous solutions and organic solvents.

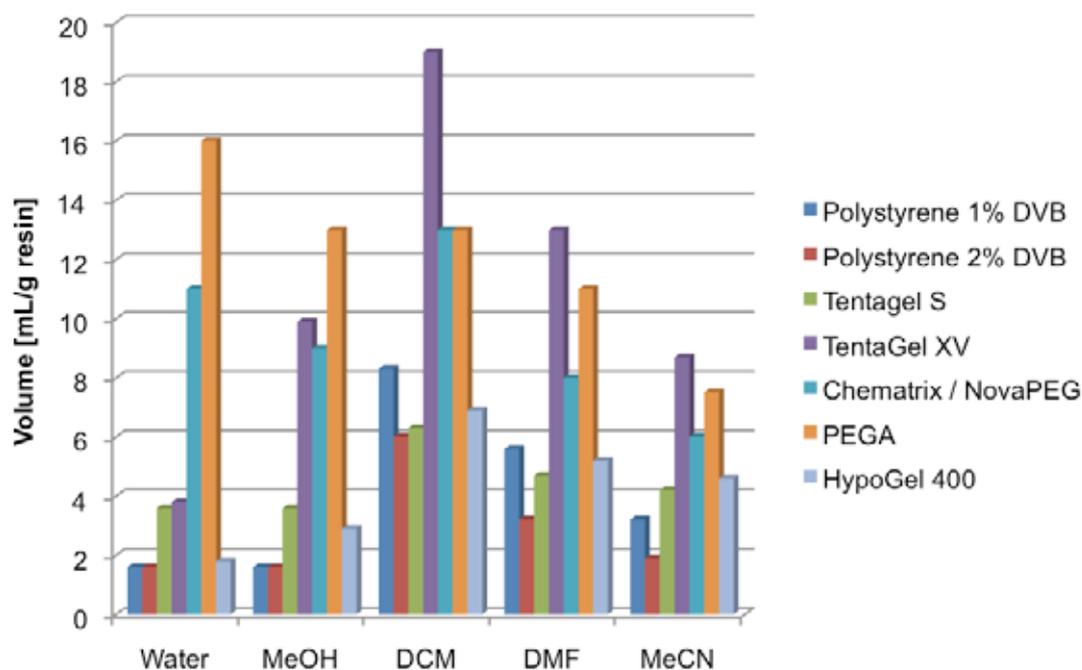

Fig. 6: Swelling characteristics of differently functionalized resins. Depending on the intended use and reaction conditions, resins optimized for hydrophilic and more hydrophobic solvents are available.

Not only spacers have an influence on the swelling properties, but also the crosslinking of the core resin. For TentaGel resin a reduction of the polystyrene core crosslinking resulted in higher swelling properties of the extended volume (XV) resin versus the original Tentagel S polymer [9; 10; 11]. High swelling creates an extended reaction space, which is a prerequisite for the synthesis of difficult sequences, aggregating peptides, mini proteins and PNAs in high purities and good yields (Figure 7).

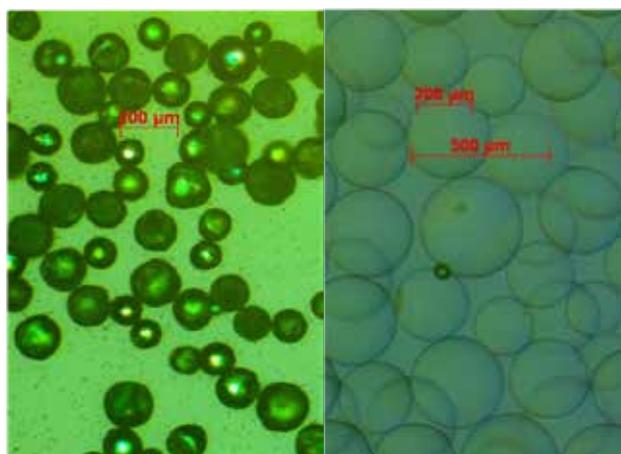

Fig. 7: TentaGel resin as seen under the microscope. Left: dry TentaGel XV. Right: TentaGel XV swollen in DMF, showcasing the resin's eponymous extended volume which is useful for the synthesis of long and difficult sequences.

2.3 Resin Substitution

Another important characteristic of solid supports is the quantity of accessible functional groups. The number of these reactive sites is expressed in millimoles per gram of resin and is called the resin substitution. When loading amino acids to a resin and determining this loading gravimetrically, the loading will be higher for amino acids with lower MW than for heavier amino acids. This fact results from the increasing weight of the loaded resin with growing MW of the attached amino acid and the proportional decrease of millimoles per gram. This is summarized in the following formula for weight gain substitution:

$$S_{(wt)} = \frac{Wt_{(g)} \cdot 1000}{Wt_{(add)} \cdot Wt_{(t)}}$$

$S_{(wt)}$: weight gain substitution [mmol/g]

$Wt_{(g)}$: weight gained by resin [g]

$Wt_{(add)}$: molecular weight added to the resin; MW of amino acid minus MW of leaving group [g/mol]

$Wt_{(t)}$: total weight gain of the resin after loading [g]

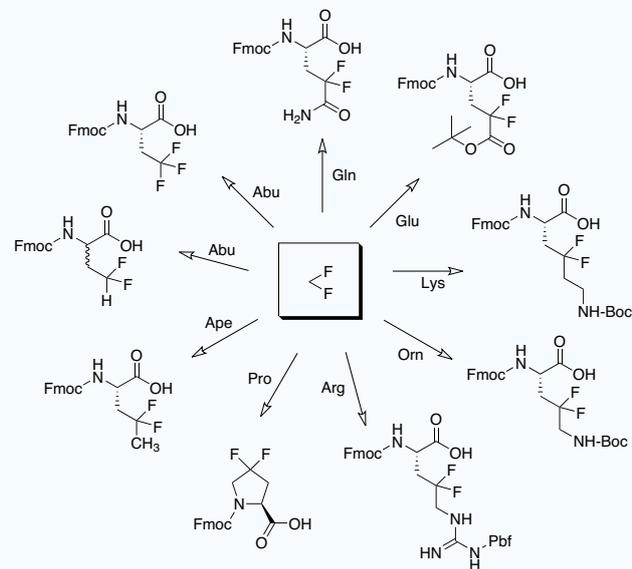

The chemical nature of the reactive sites for the different resins with their cleavage conditions, specific uses, synthetic strategies, and protocols how to attach amino acids to the resins are described below.

For long or difficult sequences it is often beneficial to choose a resin with low substitution, as possible side-reaction are avoided through lower local peptide concentration and enhanced reaction space on the resin.

γ,γ -Difluoro Amino Acids

The incorporation of fluorine building blocks into peptides may result in: increased chemical and thermal stability, resistance to degradation by proteases, and enhanced lipophilicity.

Appropriate peptides display better affinity to lipid membranes and stronger interactions with receptors. Stabilization of particular conformations and auto-assembly can be induced. These amino acids can also be useful as label for ^{19}F -NMR studies studies.

Inquire for the γ,γ -Difluoro Amino Acids of your choice!

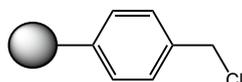

3. Base Resins

The basis resins for SPPS have functional groups that will generate a very stable bond to the molecules attached to the solid support. This is why these resins are not employed directly in SPPS, but usually serve as basis for further modifications. Common to all of these resins is that they are based on polystyrene and require harsh acidic conditions to cleave the final product. Resins that are functionalized with specific linkers are discussed in the subsequent chapter.

3.1 Merrifield Resin

Merrifield resin is a polystyrene polymer crosslinked by DVB that carries a chloromethylene group attached to the polystyrene backbone as reactive group to attach amino acids. Usually the functional group of the resin is incorporated by electrophilic aromatic substitution. However, copolymerization can also be used, which results in a more uniform final resin that may exhibit improved swelling properties well as more uniform reaction kinetics [12].

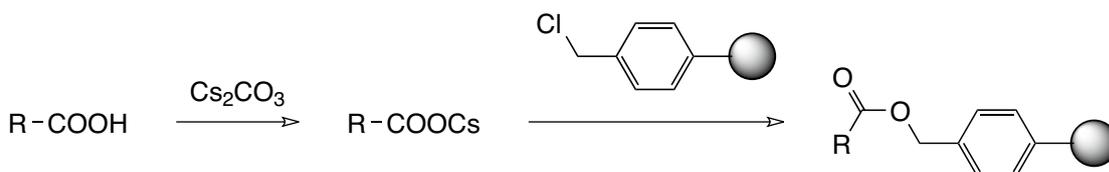

The standard Merrifield resin often serves as basis for other resins that use linkers to introduce a different swelling behavior, or reactive groups that allow for different chemistries and synthetic strategies.

The cleavage of substrates from Merrifield resin requires highly acidic conditions and specialized equipment. Aside from the standard HF procedure, low-high HF methods, as well as trifluoromethanesulfonic acid (TFMSA) and low-high TFMSA protocols can be employed [13; 14; 15; 16; 17; 18; 19].

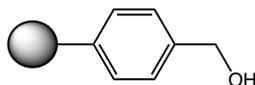

Protocol 1: Attachment of Carboxylic Acids to Merrifield Resin [20]

- | | |
|--|--|
| <p>I. Dissolve 1 mmol of carboxylic acid in 5 mL methanol and add 0.5 mL water.</p> <p>II. 20% aq. Cs_2CO_3 is added to adjust the solution to pH 7.</p> <p>III. The solution is evaporated to dryness under reduced pressure.</p> <p>IV. Add 2.5 mL DMF to the residue and evaporate to dryness under reduced pressure.</p> <p>V. Repeat step IV.</p> <p>VI. Swell the resin for 1 h in DMF (6-8 mL per gram of resin) for 1 h in a flask with heating mantle, thermometer on an orbital shaker.</p> <p>VII. Add 1 eq. (based on the chlorine substitution of the resin) of carboxylic acid caesium salt to the resin.</p> | <p>Note: the caesium salt must be absolutely dry to achieve optimal results</p> <p>VIII. The mixture is shaken at 50 °C for 24 h.</p> <p>IX. Remove solution by filtration and wash the resin with DMF, followed by 50% (v/v) aq. DMF, then 50% (v/v) aq. methanol and finally pure methanol.</p> <p>X. Dry resin to constant weight under reduced pressure.</p> <p>Note: If desired, the reaction can be checked for completeness by treating an aliquot of the resin with a solution of 4-(4-nitrobenzyl)pyridine in DMF/DCM [21]. Alternatively to this caesium salt based method a potassium fluoride method can be employed [22; 23].</p> |
|--|--|

3.2 Hydroxymethyl Resin

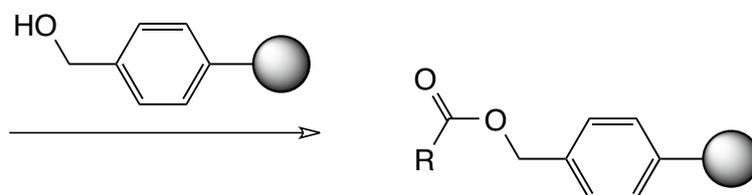

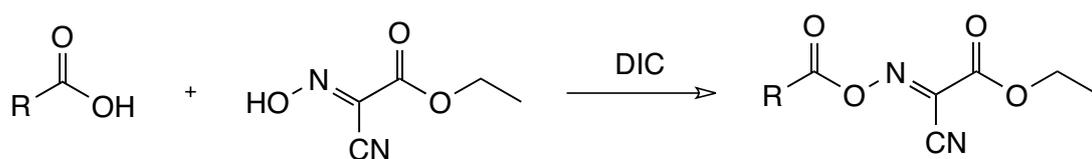

In contrast to the chloromethyl functionalized Merrifield resin, the hydroxymethyl analog exists to avoid unwanted side reaction. After incomplete resin loading, unreacted chloromethyl groups in the Merrifield resin can cause side reactions during peptide synthesis [24; 25]. In order to avoid such side reactions, remaining free hydroxyl groups can be capped with acetic anhydride.

The conditions for cleaving substrates from the hydroxymethyl resin are the same as for the conventional Merrifield resin.

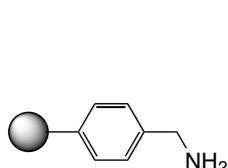

Protocol 2: Attachment of Carboxylic Acids to Hydroxymethyl Resin

- I. Swell the resin in DMF using 15 mL solvent per gram of resin.
- II. Dissolve 1.5 to 2.5 eq. (relative to the reactive sites on the resin) of carboxylic acid in another vessel with a minimum amount of DMF.
- III. Add the same amount of eq. of OxymaPure and dissolve. If necessary add more DMF.
- IV. Add the solution to the resin.
- V. Dissolve 0.1 eq. (relative to the reactive sites on the resin) of DMAP in a minimum amount of DMF in a separate vessel.
- VI. Add 1.0 eq. (relative to the amino acid) of DIC to the resin and subsequently add the DMAP solution and close the container with a drying tube.
- VII. Shake the solution for 2 to 3 h at room temperature.
- VIII. Add 2 eq. (relative to the reactive sites on the resin) of acetic anhydride and pyridine to the mixture and shake for 30 min.
- IX. Remove solution by filtration and wash the resin 3 times with DMF, 3 times with DCM, and finally 3 times with methanol.
- X. Dry resin to constant weight under reduced pressure.

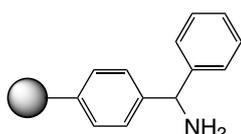

3.3 Amino Core Resins

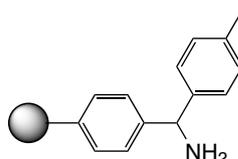

Amino core resins were originally developed for preparing C-terminal peptide amides via the Boc SPPS strategy. The aminomethyl (AM) resin is structurally similar to the Merrifield and hydroxymethyl resin having an amino group instead of a chloro or hydroxyl group, respectively [26; 27]. Additionally, two sterically more demanding resins have been developed with the benzhydrylamine (BHA) [28; 29; 30] and 4-methylbenzhydrylamine (MBHA) resins [31; 32]. Although the BHA and especially the MBHA resin are more sensitive to acid than the AM resin, they still require harsh acidic conditions (HF or TFMSA) for the final product cleavage.

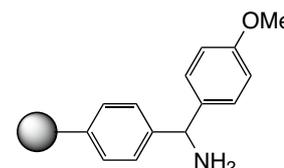

AM resin
aminomethyl polystyrene

BHA resins
benzhydrylamine
polystyrene

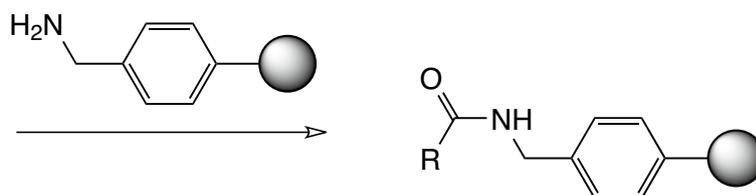

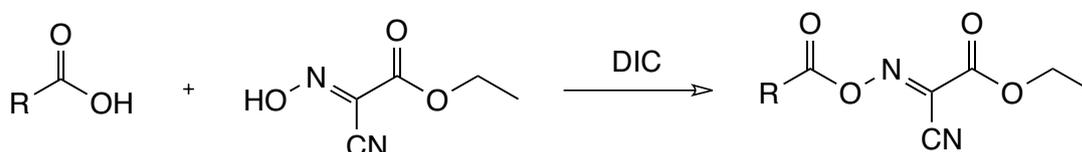

MBHA resin
4-methyl-benzhydrylamine
polystyrene

MeO-BHA resin
4-methoxy-
benzhydrylamine
polystyrene

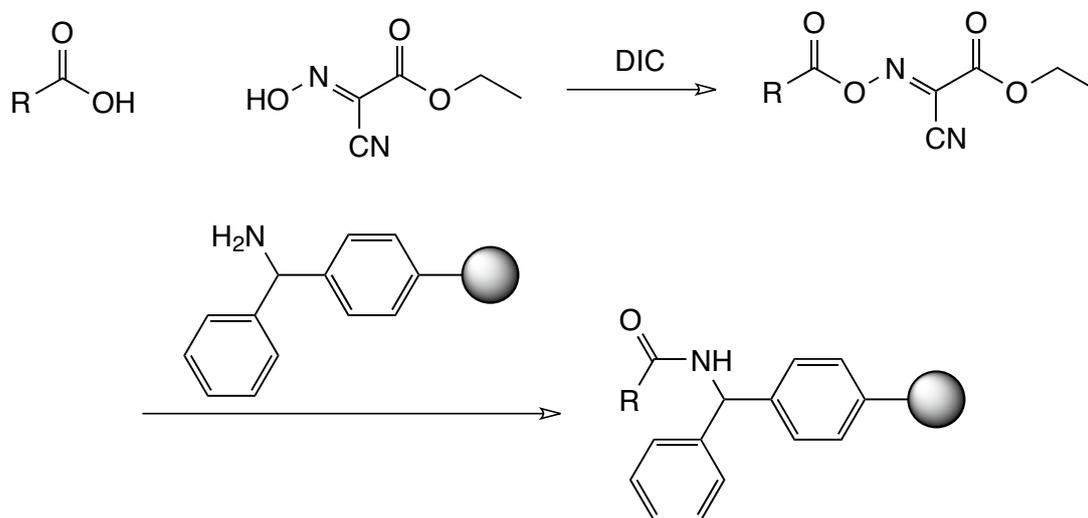

Protocol 3: Attachment of Carboxylic Acids to Aminomethyl Resin

- I. Swell the resin in DMF using 15 mL solvent per gram of resin.
- II. Dissolve 1.5 to 2.5 eq. (relative to the reactive sites on the resin) of carboxylic acid in a separate vessel with a minimum amount of DMF.
- III. Add the same number of equivalents of OxymaPure and dissolve. If necessary add more DMF.
- IV. Add the solution to the resin.
- V. Add 1.0 eq. (relative to the amino acid) of DIC to the container with the resin and close the vessel with a drying tube.
- VI. Shake the solution for 2 to 3 h at room temperature.
- VII. Add 2 eq. (relative to the reactive sites on the resin) of acetic anhydride and pyridine to the mixture and shake for 30 min.
- VIII. Take a small sample of resin, wash with DCM and perform a Kaiser test. If free amines are detected, repeat step VII. with 1 eq. of reagents.
- IX. Remove solution by filtration and wash the resin 3 times with DMF, 3 times with DCM, and finally 3 times with methanol.
- X. Dry resin to constant weight under reduced pressure.

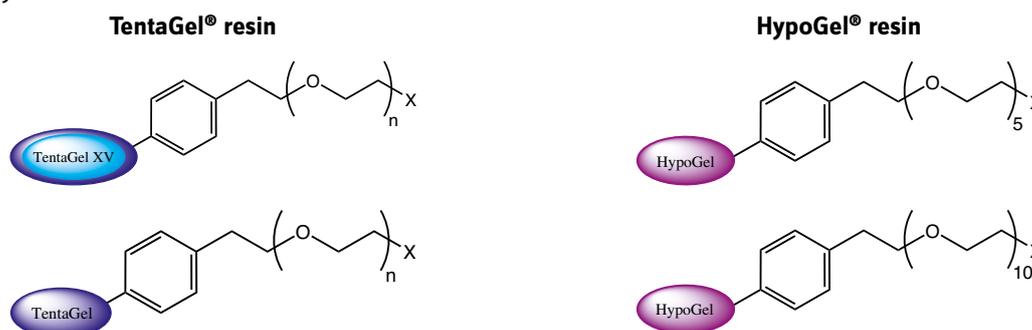

Protocol 4: Attachment of Carboxylic Acids to BHA or MBHA Resin

- I. Swell the resin in 10% (v/v) DIPEA in DCM using 10 mL solution per gram of resin for 15 min in an agitated reactor.
- II. Filter off the solution and wash with DCM.
- III. Add 10 mL of DMF to the resin.
- IV. Dissolve 1.5 to 2.5 eq. (relative to the reactive sites on the resin) of carboxylic acid in another container with a minimum amount of DMF.
- V. Add the same number of equivalents of OxymaPure and dissolve. If necessary add more DMF.
- VI. Add the solution to the resin.
- VII. Put the resin mixture in an ice bath and add 1.0 eq. (relative to the amino acid) of DIC to the resin when the mixture has cooled down. Close the vessel with a drying tube and mix contents by gently moving the vessel.
- VIII. Remove the ice bath and let the mixture warm up to RT.
- IX. Shake the solution for 4 h at RT.
- X. Take a small sample of resin, wash with DCM and perform a Kaiser test. If free amines are detected continue to step XI. Otherwise continue with step XIII.
- XI. Add 2 eq. (relative to the reactive sites on the resin) of acetic anhydride and pyridine to the mixture and shake for 30 min.
- XII. Take a small sample of resin, wash with DCM and perform a Kaiser test. If free amines are detected repeat step XI.
- XIII. Remove solution by filtration and wash the resin 3 times with DMF, 3 times with DCM, and finally 3 times with methanol.
- XIV. Dry resin to constant weight under reduced pressure.

3.4 TentaGel® Resins

TentaGel® resins have been developed for the use in polar solvents which are largely incompatible with the traditional polystyrene resins. Through the attachment of polyethyleneglycol (PEG) chains to the polystyrene core, the swelling behavior, especially in hydrophilic solvents such as water and methanol, is considerably increased (Figure 6) which allows for a broader range of chemistry [33]. Apart from the swelling behavior, the more hydrophilic environment decreases the repulsion of charged organic intermediates formed during reactions. For the base resin, a range of functional groups is available ranging from electrophilic bromine leaving groups [33] to nucleophilic groups like hydroxy [34; 35], amino [36], and carboxy functions [37].

TentaGel S (R and HL) and TentaGel XV are bearing PEG spacers of 3000 Da, while TentaGel XV is less cross-linked, in order to develop higher swelling properties.

HypoGel 200 and HypoGel 400 resins are bearing PEG spacers of 200 (n=5) and 400 Da (n=10) respectively.

For the synthesis of hydrophobic peptides, long peptides and other challenging molecules, it has been demonstrated that an increased swelling volume of the base resin leads to higher yield and purity. In this context, ChemMatrix and TentaGel® XV (XV = extended volume) have been developed and show superior results. The high swelling creates an extended reaction volume which provides the ideal conditions for the synthesis of difficult sequences, aggregating peptides, mini proteins and PNAs in high purities and yields.

The polar PEG spacers allow the composite resin to swell in a wide range of solvents including water, methanol, DMF and DCM, while the handling is still easy and comparable to standard TentaGel resins.

However, a high resin swelling results in a high consumption of solvents. In case increased solubilizing properties are not required, resins with PEG chains shorter than 3000 Da exhibit sufficient solubilizing property with reduced solvent volume consumption. For such purposes, HypoGel 200 and HypoGel 400 have been developed.

Resin/ Solvent	H ₂ O	MeOH	EtOH	DCM	Toluene	DMF	NMP	MeCN	THF	Dioxane	Ether
Polystyrene 1% DVB	-	1.6	1.7	7.5	7.5	4.1	7.0	2.0	7.5	7.0	3.5
TentaGel® S 0.25-0.3 mmol/g	3.6	3.6	2.9	6.3	4.8	4.7	4.9	4.2	5.0	5.4	1.9
HypoGel® 200 0.7-0.9 mmol/g	1.8	2.8	2.6	7.0	5.1	6.0		3.0	6.5	6.4	
HypoGel® 400 0.6-0.8 mmol/g	1.8	2.9	2.8	6.9	5.5	5.2		4.6	5.3	5.6	2.6
TentaGel XV 0.2-0.4 mmol/g	3.6	6.2	2.2	18.0	12.6	13.2	14.4	8.6	13.4	14.2	2.0

Tab. 2: Swelling volume of polystyrene and different PEG grafted polystyrene resins in different solvents

General Procedure for Measurement of Resin Swelling:

To remove soluble by-products and impurities, the resin has to be washed with toluene, DCM, DMF and MeOH (5 times for each solvent) and dried. To 1 g of dry resin solvent is added in a 10-15 ml graduated cylinder, and the resin is mixed with 12-18 ml of solvent. The cylinder is sealed and after 2 h the resin is stirred again to remove all remaining air bubbles and to form a homogenous resin suspension. The cylinder is sealed again and after 22 h of settlement the resin volume is measured [38].

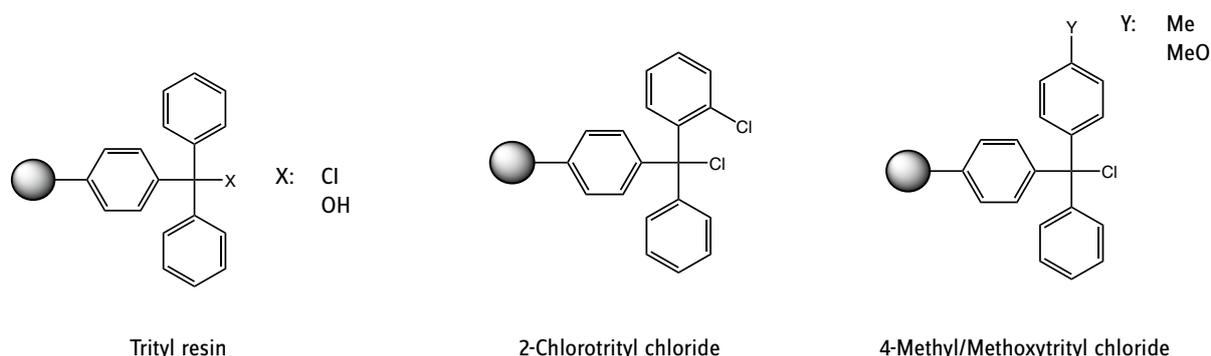

4. Resins and Linkers for the Synthesis of Peptide Acids

The major driver and advantage of using additional linkers attached to a basis resin are the milder cleavage conditions and a greater variety of functional groups, allowing more and advanced synthetic strategies. Depending on the desired swelling properties and reaction conditions the linkers can be combined with any of the aforementioned basic resins and tailored to the intended use.

4.1 Trityl Resins

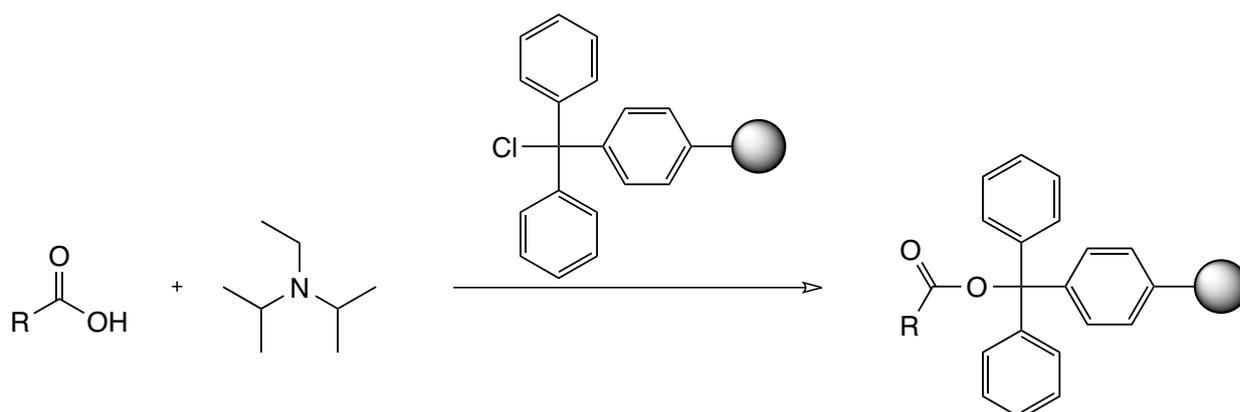

Resins functionalized with trityl linkers are highly acid sensitive, as the three phenyl rings stabilize the benzylic carbocation that is generated during cleavage. These cleavage conditions are so mild that only 1% of TFA is needed, and even less acidic protocols using 20% hexafluoroisopropanol (HFIP) are sufficient to cleave the products from the resin. Peptides can therefore be cleaved from the resin with all side chain protecting groups in place and the N- and C-terminus separately modified e.g. by head-to-tail cyclization or fragment condensation.

Various trityl-based linkers exist with different substitutions on the trityl group that fine-tune the cleavage conditions. The most popular of these in peptide chemistry is the 2-chlorotrityl chloride resin 2-CTC [39; 40; 41]. Especially for the attachment of alcohols, phenols, thiols and amines the 4-Methyltrityl (Mtt), 4-Methoxytrityl (Mmt) and 4,4'-Dimethoxytrityl (Dmt) resins can be employed. Aside from being used as a linker for resins, both the Mtt and Mmt group are also employed for side chain protection of Lys and His. Besides the ready-to-use chloride resin, hydroxyl variants are also available that have to be chlorinated before loading the amino acids.

Those trityl linkers open up new chemical pathways for modifications after the peptide chain has been built up. Besides that the steric demand of the trityl group prevents side reactions with proline or N-alkyl amino acids at the C-terminus. If proline is the first or second amino acid at the C-terminus of a peptide, spontaneous diketopiperazine formation can occur and cleave the peptide from resins. The steric hindrance of trityl linkers is sufficient to prevent this diketopiperazine formation [42; 43].

Moreover, racemization-prone amino acids such as Cys and His can be attached without enantiomerization [39], and the reattachment of Met and Trp residues to the resin during the cleaving procedure is minimized.

Protocol 5: Attachment of Carboxylic Acids to Trityl Chloride Resins [44]

Note: It is important to use dry solvents and reaction containers.

- I. Pre-swell resin in dry DCM (10 mL/g resin) for 15 min
- II. Dissolve 1.2 eq. of carboxylic acid in dry DCM
- III. Add 2.5 eq. of DIEA to the solution. This addition can aid the dissolution of the acid.
- IV. Filter the excess DCM from the resin and add the reaction mixture.
- V. Shake mixture for 1 h at room temperature.
- VI. In order to cap the remaining reactive trityl group, add 1 mL of a solution of methanol and DIEA (5:1; v:v) per gram of resin and agitate the resin for 15 min.
- VII. Discard the reaction solution and wash the resin 5 times with DCM and 3 times with methanol.

VIII. Dry resin to constant weight under reduced pressure.

IX. The loading can be estimated gravimetrically using the formula below:

$$n = \frac{(m_2 - m_1) \cdot 1000}{(MW_{\text{Xaa}} - 36.46) \cdot m_2}$$

n = loading of the resin [mol/g of resin]

m_1 = weight of resin before loading [g]

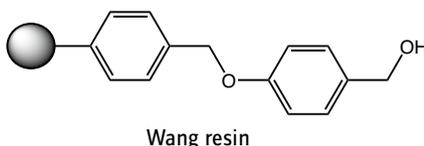

m_2 = weight of resin after loading [g]

MW_{Xaa} = molar weight of attached amino acid [g/mol]

36.46 g/mol is the molecular weight of HCl, which is removed and be replaced by the amino acid

4.2 Wang Resins

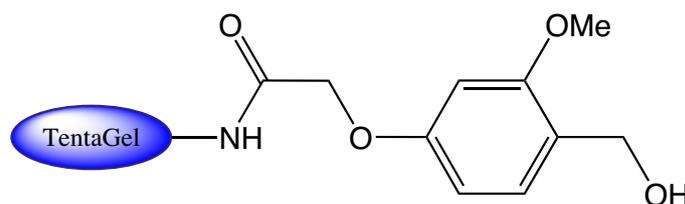

The Wang resin might at first glance look very similar to the original Merrifield resin, but the cleavage conditions are significantly milder (50% (v/v) TFA in DCM) due to the alkoxy group of the *para* alkoxybenzyl alcohol linker [45; 46]. These mild cleavage conditions have made the Wang resin popular not only in the peptide field, but also among organic chemists in general, as it can also be used to attach e.g. phenols and alcohols [47; 48; 49].

To load the Wang resin with carboxylic acids, protocol 2 can be employed.

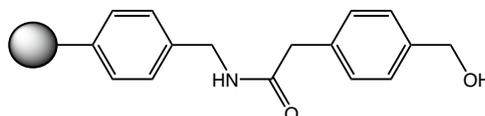

4.3 AC Resin

The 4-hydroxymethyl-3-methoxyphenoxyacetic (AC; sometimes also MHMPA) linker is even more acid labile than the Wang resin due to an additional methoxy group on the aromatic ring. The peptide acid can be cleaved from the resin with 1% TFA while all the side-chain protecting groups are retained [50].

4.4 PAM Resin

The 4-Hydroxymethyl-phenylacetamidomethyl functionalized PAM resin is widely used in Boc-chemistry, as it is more stable towards acids and allows the synthesis of medium-sized to large peptides [51; 52; 53].

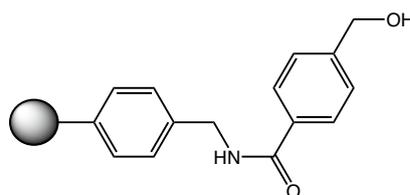

PAM resin

Protocol 2 is suitable to load carboxylic acids on the PAM resin, and cleavage is achieved similar to the Merrifield resin.

4.5 HMBA Resin

Resins with hydroxymethylbenzoic acid (HMBA) linkers are regarded as one of the most versatile solid supports for SPPS [54]. HMBA linkers are attached to amine base resins and are stable to acidic cleaving conditions. In contrast to the other resins and linkers highlighted before, the cleavage from the resin is achieved by a range of nucleophiles, thus various C-terminal modifications such as alcohols, methyl esters, hydrazides or amides can be synthesized.

HMBA resin

Similar to Wang and PAM resins, protocol 2 can be used to load carboxylic acids to the HMBA resin.

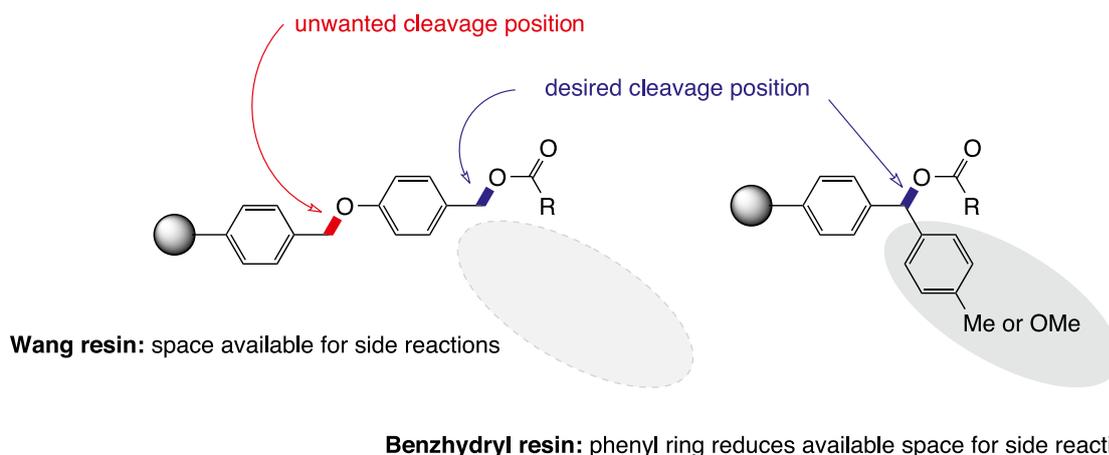

4.6 Benzhydryl Resins

Using the *p*-Hydroxybenzyl linker (Wang linker) is one of the most frequently applied methodologies to prepare peptides with C-terminal carboxylic acid functions. However, many side reactions have meanwhile been discovered that challenge synthetic chemists to find appropriate purification methods.

During final treatment, concentrated TFA cleaves the peptide not only at the carboxyl function (the desired position), but also at the phenoxy group, resulting in the formation of unwanted peptide esters. Additionally, alkylation of certain side chains, such as Trp or Tyr may occur. These impurities may be difficult to separate from the desired product [55; 56; 57; 58; 59].

Another common type of side reaction observed during peptide synthesis on Wang resin is the formation of diketopiperazines by the amino acids on position 1 and 2 of the C-terminus. It becomes a major issue if Pro, Gly or any N α -methylated amino acids are located on position 1, whereas Lys or amino acids with NH₂-bearing side chains are present on position 2 (Lys, Orn, Dab or Dap). A typical side reaction observed when Cys is present at the first position of the C-terminus is the substitution of the thiol group by piperidine during Fmoc removal, leading to the formation of 2-(1-piperidyl)alanine [60].

Consequently, the final yield may be significantly reduced during peptide synthesis on Wang resin, which affects the cost/efficiency balance in commercial productions. Therefore, new types of resins, like 2-chlorotrityl resin, where such side reactions are excluded by the design of resin and linker, are increasingly becoming the preferred choice of solid support for peptide synthesis.

Another alternative type of solid support that is less prone to side reactions than Wang-resins are benzhydryl-based resins. As there is no phenoxy group present, no related side reactions leading to benzyl esters or peptides with alkylated residues can occur. In case of 4-methylbenzhydryl resin, an additional tolyl group is placed as residue. As this does not contribute much to the stability of the resulting carbocation produced during cleavage, conditions are similar to the cleavage conditions typically applied for Wang resin. At least 25% of TFA in DCM with scavengers will liberate the peptide from the resin at room temperature within 30 min.

In case a more acid sensitive resin is required, for example for the production of protected peptide fragments, typically 2-chlorotrityl resin is being used. However, if the sterical hindrance becomes too high, 4-methoxybenzhydryl resin can be used as an alternative [61; 62].

Protocol 6: Attachment of Carboxylic Acids to 4-Methylbenzhydryl Resin [63; 64]

Note: It is important to use anhydrous solvents and dry reaction vessels.

- I. Weigh out 1 mmol of 4-methylbenzhydryl bromide resin in a flask.
- II. Add DCM and let the resin swell for 15 to 20 min.
- III. Filter and wash the resin with DCM.
- IV. Weigh 2 mmol of carboxylic acid, 2 mmol of CsI, 4 mmol DIPEA and add DMF. Let the mixture stand until the solution becomes clear.
- V. Add the mixture to the swollen resin and let it react for 14 h at 20°C to 25°C.
- VI. Add MeOH and shake for 2 h.
- VII. Filter off the resin and wash 6 times with DMF and 4 times with DCM.

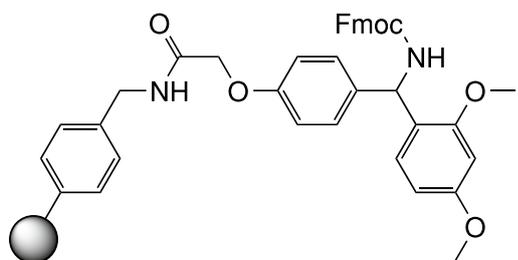

5. Resins and Linkers for the Synthesis of Peptide Amides

5.1. Rink Amide and Knorr Resins

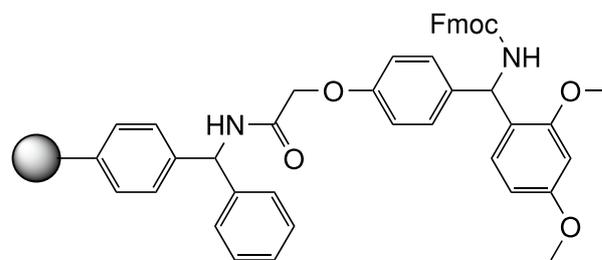

C-Terminal amides are the most common modification in peptides. For their synthesis *via* the Fmoc strategy the Rink amide linker has been developed [65; 66]. The amino group of the Rink linker for amide synthesis is protected with Fmoc (see below), while the corresponding Rink acid linker bears a hydroxyl group instead of the amine (not shown).

Different modifications of the Rink linker have been developed towards varying uses. The standard Rink amide resin is cleaved in 10% TFA in DCM, as higher concentrations of acid can cleave the Rink linker from the polystyrene resin, producing highly colored impurities. The formation of these byproducts can be minimized by adding trialkylsilanes to the cleavage mixture. The Knorr resin avoids this unwanted linker cleavage through the introduction of a more stable acetamide spacer between the Rink linker and the resin [67].

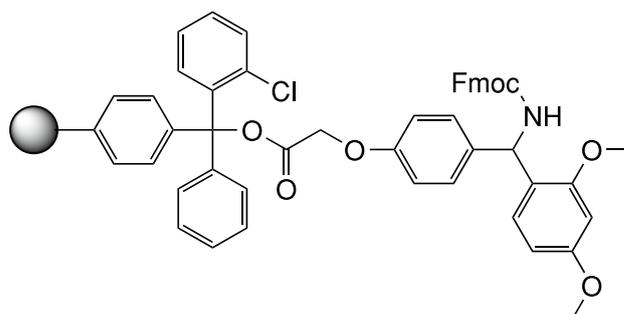

An additional variant of the Knorr linker is the attachment to an even more acid labile 2CT resin. Through this combination, the protected peptide can be cleaved from the 2CT resin while still carrying the Knorr linker as protecting group for the C-terminus for subsequent modifications using solution phase chemistry. This strategy can be especially useful for synthesizing large peptides *via* ligation that have difficult sequences in the C-terminal region.

Rink amide resin

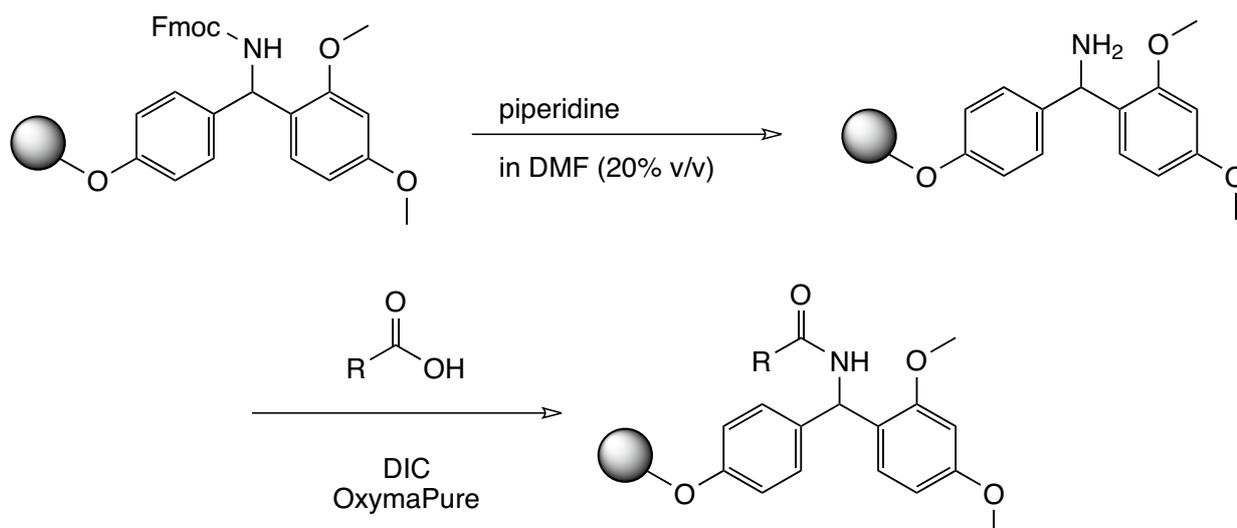

Rink MBHA resin

Rink-2-chlorotrityl resin

Loading amino acids to the Rink amide resins is essentially the same reaction sequence as for standard peptide coupling, with a Fmoc deprotection step followed by the coupling reaction.

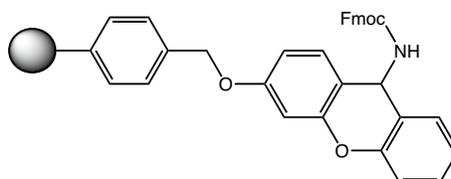

Protocol 7: Attachment of Carboxylic Acids to Rink Amide Linker Resins

- I. Swell the resin in DMF using 15 mL solvent per gram of resin.
- II. Discard excess liquid and deprotect Fmoc group from the linker with 15 mL of 20% (v/v) piperidine in DMF for 10 min.
- III. Repeat step II with 5 min reaction time.
- IV. Discard the piperidine solution and wash 5 times with DMF.
- V. Dissolve 1.5 to 2.5 eq. (relative to the reactive sites on the resin) of carboxylic acid in a second vessel with a minimum amount of DMF.
- VI. Add the same number of equivalents of OxymaPure and dissolve. If necessary add more DMF.
- VII. Add 1.0 eq. (relative to the amino acid) of DIC to the vessel with the amino-acid/OxymaPure solution and close the vessel with a drying tube. Let the solution stand at RT for 10 min.
- VIII. Add the reaction solution to the resin.
- IX. Shake the solution for 2 to 3 h at room temperature.
- X. Take a small sample of resin, wash with DCM and perform a Kaiser test. If free amines are detected, continue with step XI, otherwise with step XII.
- XI. Add 1 eq. (relative to the reactive sites on the resin) of acetic anhydride and pyridine to the mixture and shake for 30 min.
- XII. Remove solution by filtration and wash the resin 3 times with DMF, 3 times with DCM, and finally 3 times with methanol.
- XIII. Dry resin to constant weight under reduced pressure.

5.2 Sieber Resin

The Sieber amide resin is ideally suited to synthesize side-chain protected peptide amides, as cleavage occurs in 1% TFA in DCM [68]. Since the Sieber linker is less bulky through the fixation of the two aryl rings *via* the phenolether bridge, it is better suited for the synthesis of C-terminal secondary amides [69].

Sieber amide resin

A protocol similar to the Rink amide resin loading protocol No. 6 (chapter 5.1) can be employed to attach the first amino acid to the solid support.

5.3 Peptide Amides Synthesis by Side Chain Immobilization

As an alternative to using linker chemistry to generate C-terminal amides, if the first amino acid to be attached to the solid support bears a side chain with a suitable functional group (such as an OH-group), the carboxamide of this amino acid can be attached to the resin *via* its side chain. The peptide chain can then be extended through standard SPPS to generate the desired peptide amide (Figure 8). Many amino acids and peptides as well as preloaded resins are commercially available for fast and easy access.

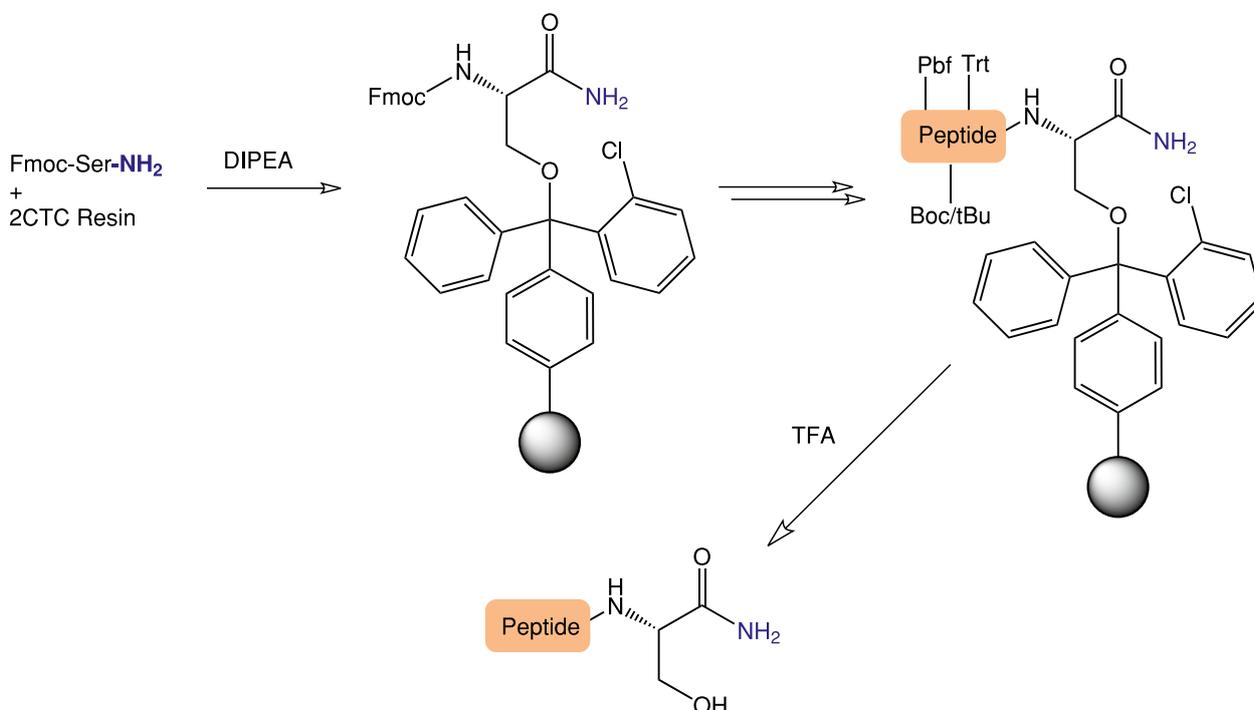

Fig. 8: Example of an alternative way of synthesizing peptide amides by attaching a peptide amide *via* the side chain to the solid support which can subsequently be extended by SPPS.

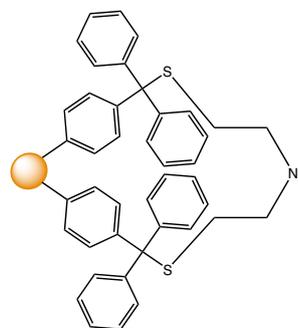

6. Resins for the Synthesis of Peptide Thio Esters

6.1. SEA Resins

Additionally to the peptide acids and amides the corresponding thio esters are becoming increasingly important, especially for the native chemical ligation to synthesize large peptides by fragment condensation.

Peptide thio esters can be conveniently generated by using the bis(2-Sulfanylethyl)amino (SEA) linker on a trityl resin [70; 71; 72; 73].

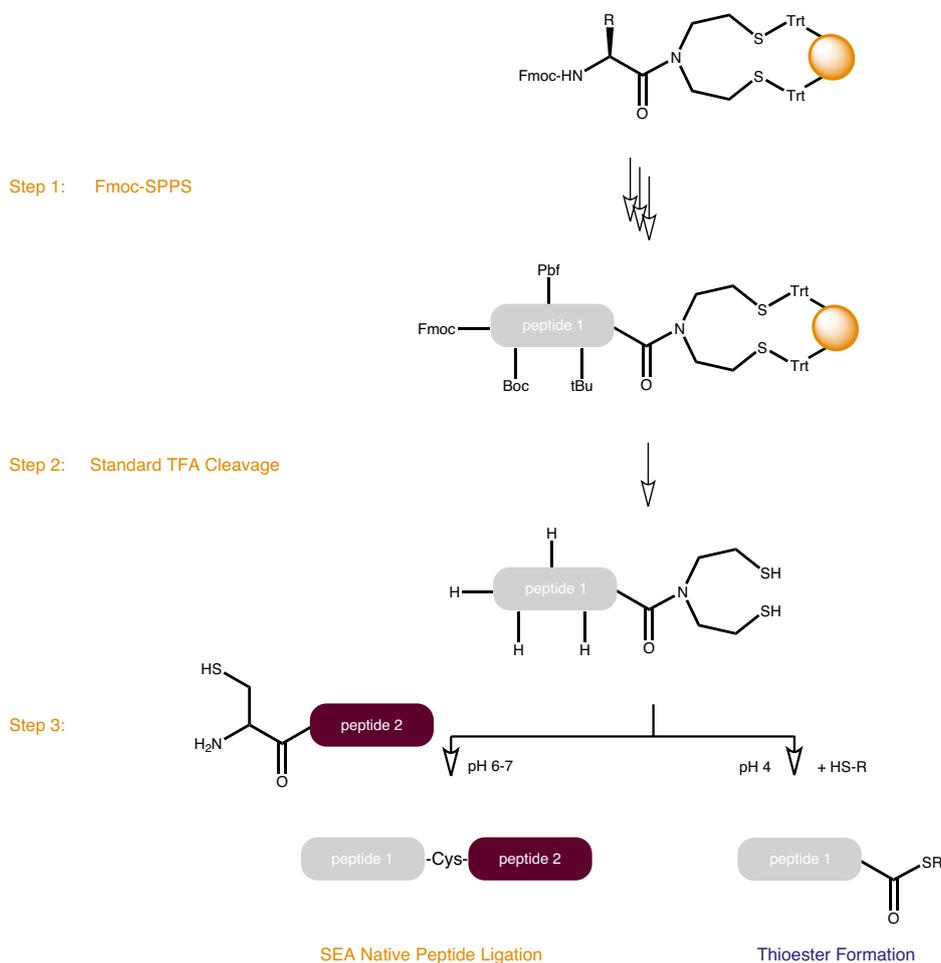

The thioester is generated after synthesizing the peptide on the SEA resin by cleaving it with TFA. An intermediary compound with disulfide cycle can be isolated and stored and activated *in situ* when needed.

SEA resin

SEA Resin [**SEA** = bis(2-Sulfanyl**E**thyl)**A**mino] is an innovative solid support offering a vast array of tools for efficient synthesis of long peptides through consecutive different ligation technologies performed in a one-pot assembly.

- ✓ SEA resin is an innovative solid support offering a vast array of tools for efficient synthesis of long peptides.
- ✓ SEA resin yields SEA peptides which can be ligated directly with Cys peptides using SEA native peptide ligation.
- ✓ SEA resin gives easy access to peptide thioesters and thus implies convenient synthesis of long peptides through Native Chemical Ligation (NCL).

Principles:

1. The first amino acid should be loaded onto SEA resin using HATU activation. Alternatively, preloaded SEA resins are available loaded with all 20 proteinogenic amino acids. The peptide can then be designed applying conventional Fmoc/*t*Bu protocols for batch solid phase peptide synthesis (1st step). For Cys within the sequence Fmoc-Cys(S-*t*Bu)-OH (FAA1575) should be used.

Protocol SEA 1: Protocol 1: Loading SEA Resin

- | | |
|---|--|
| <p>I. Pre-swell the resin (0.1 mmol) in DCM for 60 min and wash with DMF.</p> <p>II. Rapidly dissolve the Fmoc amino acid (1 mmol), the activator HATU (1 mmol) and DIPEA (3 mmol) in DMF (2 mL) and immediately add to the beads. Gently agitate for 2 h. Wash with DCM.</p> | <p>III. Cap the resin twice with Ac₂O/DIPEA/DCM (10:5:85) for 2 min and then wash with DCM for 20 minutes.</p> <p>IV. Check loading by measuring the UV-absorption of the dibenzofulvene- piperidine adduct following treatment with 20% (v/v) piperidine in DMF.</p> |
|---|--|

2. Standard cleavage conditions remove the peptide from the resin including all side chain protecting groups and yield in an unprotected peptide with only the SEA group on the C-terminus (2nd step). At this point, the SEA-peptide can either be used directly for thioester formation and ligation procedures, or be purified.

3. Now SEA native peptide ligation can proceed with a second peptide fragment containing N-terminal Cys in water at neutral pH. However, in the presence of any thiol in water and at low pH, the SEA moiety is easily displaced by the thiol to give the corresponding thioester peptide (3rd step).

Protocol SEA 2: Peptide Synthesis with SEA Resin

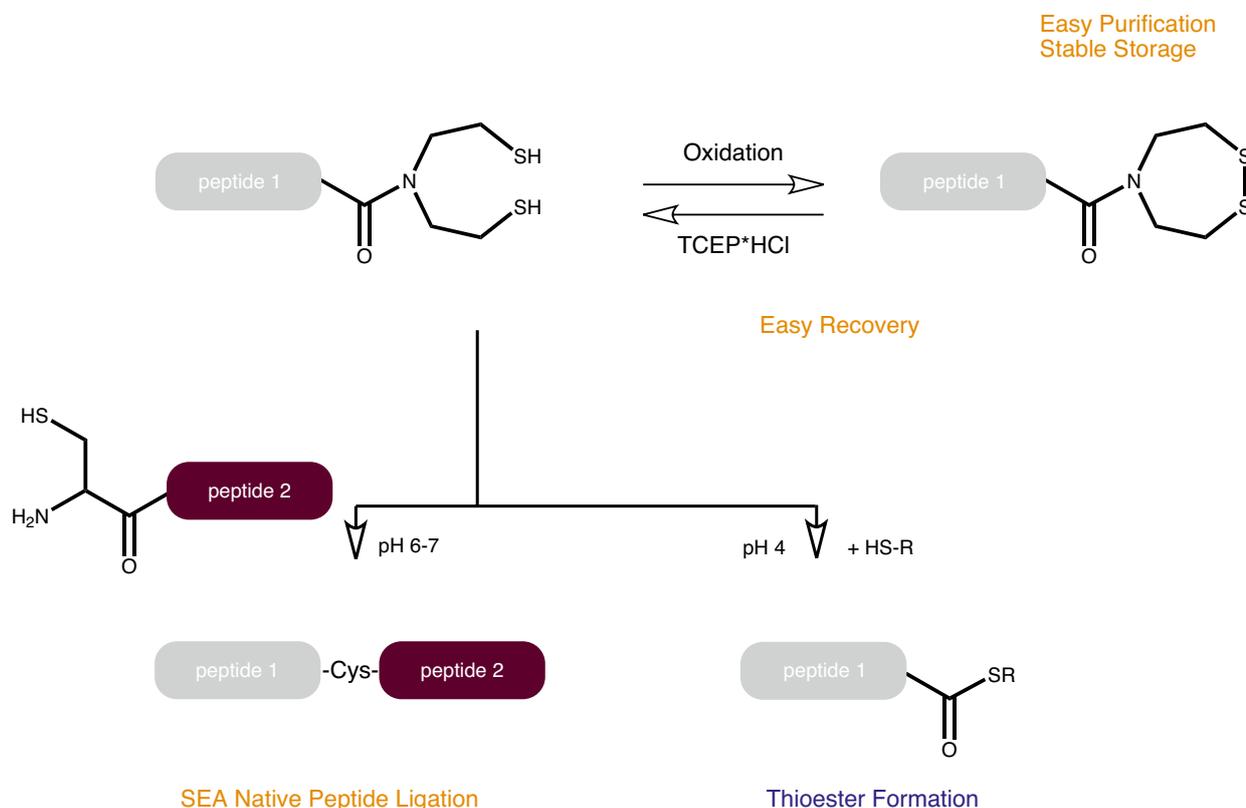

- | | |
|--|---|
| <p>I. Wash the resin with DCM and diethyl ether. Dry the resin <i>in vacuo</i>.</p> <p>II. Chain elongation is performed using standard HBTU/DIPEA conditions in any peptide synthesizer.
NB: For any internal Cys use Fmoc-Cys(S-<i>t</i>Bu)-OH as building block.</p> <p>III. Cleave the peptide with 10 mL TFA/TIS/DMF/ thioanisole/water (90:2.5:2.5:2.5:2.5) for 3 h.</p> <p>IV. Dissolve iodine (0.2 mmol) in 100 mL of DMSO.</p> | <p>V. Dissolve the peptide in AcOH/water (1:4). Add the iodine solution and agitate gently for 30 s. Add dithiothreitol (DTT) (0.1 mmol) to quench the excess of iodine.
NB: Cys(S-<i>t</i>Bu) and oxidized SEA linker are unaffected by DTT treatment, because DTT is unable to reduce disulfides at low pH. Other residues such as methionine or tryptophan are not affected during this short exposure of iodine.</p> <p>VI. Purify immediately by RP-HPLC.</p> |
|--|---|

Protocol SEA 3: Natural Chemical Ligation with SEA Peptide Fragments

- | | |
|---|---|
| <p>I. Dissolve oxidized SEA peptide (1 eq.) and N-terminal Cys-peptide (1.5 eq.) under inert atmosphere in a closed tube containing degassed ligation buffer (0.1 M phosphate buffer, 0.2 M 4-mercaptophenylacetic acid (MPAA), 0.2 M TCEP·HCl, pH 7.4). The final concentration of the peptides should be approximately 3-5 mM. Heat the mixture at 37°C under inert atmosphere.</p> | <p>II. Monitor the progress of the reaction by HPLC. For this, aliquots are acidified by addition of 10% aqueous TFA and extracted with diethyl ether to remove excess MPAA.</p> <p>III. After completion, acidify the mixture with 10% aqueous TFA, extract twice with diethyl ether and purify by standard procedure.</p> |
|---|---|

The outstanding advantage of SEA peptides:

Following cleavage, the SEA moiety can be oxidized under mild conditions (iodine) forming a stable 1,2,5-dithiazepan ring. At this stage, the oxidized SEA-peptide can very easily be purified, characterized, stored or used for other purposes. Standard protocols are available!

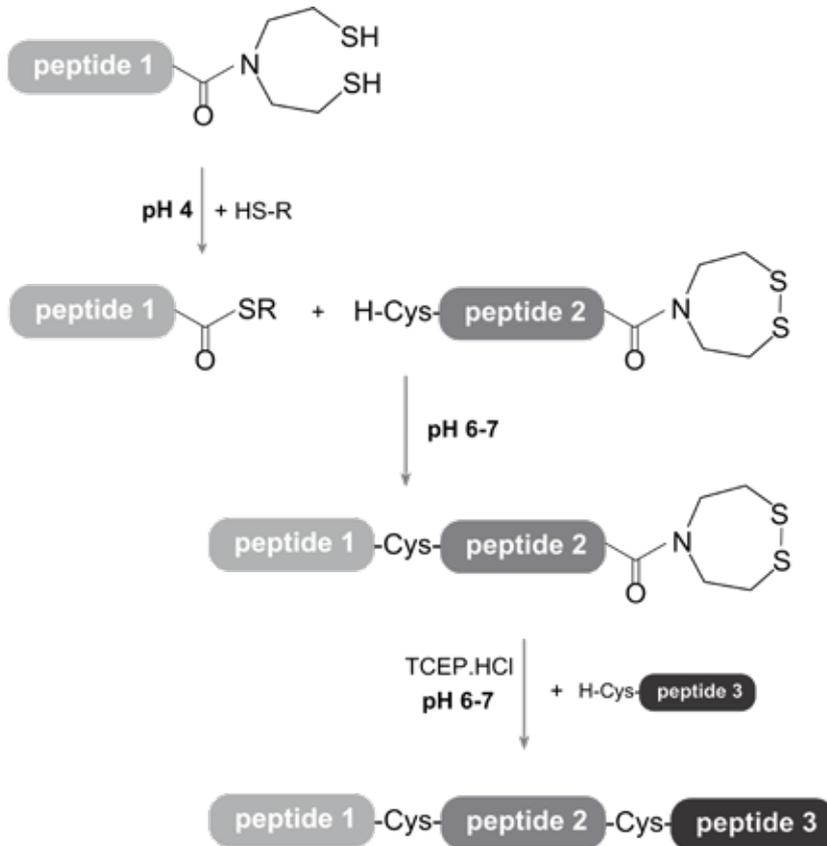

To reactivate the SEA-peptide the 1,2,5-dithiazepan ring can be opened reductively under very mild conditions with TCEP·HCl and simultaneously conjugated with an N-terminal cysteinyl-peptide or thiols forming a ligation peptide or thioester, respectively [74; 75; 76; 77; 78].

Protocol SEA 4: Synthesis of Peptide Thioesters

- I. Dissolve oxidized SEA peptide (1 eq.) under inert atmosphere in a closed tube containing degassed 0.1 M phosphate buffer, 0.2 M TCEP·HCl and 5% 3-mercaptopropionic acid (by vol.) at pH 4. The final concentration of the peptide should be approximately 1-5 mM. Agitate gently and heat the mixture at 37°C under inert atmosphere.
- II. Monitor the progress of the reaction by HPLC. For this, aliquots are acidified by addition of 10% aqueous TFA and extracted with diethyl ether to remove excess MPA.
- III. After completion - usually after 24 h - acidify the mixture with 10% aqueous TFA, extract twice with diethyl ether and purify by standard procedure.

By utilizing the SEA-technology, a one-pot three-segment ligation strategy is possible to assemble three fragments without intermediate isolation and purification.

6.2 Hydrazone Resins

Peptide hydrazides can be easily synthesized using the novel hydrazone resin. The hydrazone linker is completely stable in the course of standard Fmoc SPPS, and tolerates treatment with 5% TFA/DCM, thus permitting selective removal of Mtt or similar acid-labile protecting groups. Subsequent application of tried and tested cleavage cocktails (TFA:water:TIS 95:2.5:2.5) permits to obtain the peptides in good yields and purity [79].

Synthesized peptide hydrazides can be applied as building blocks for the conjugation to different carrier molecules using the hydrazone ligation technique, or converted to peptide thioesters which may be used in native chemical ligation (NCL).

Protocol 8: Attachment of Carboxylic Acid to Hydrazone Resin

Note: It is important to use anhydrous solvents and a dry reaction vessel.

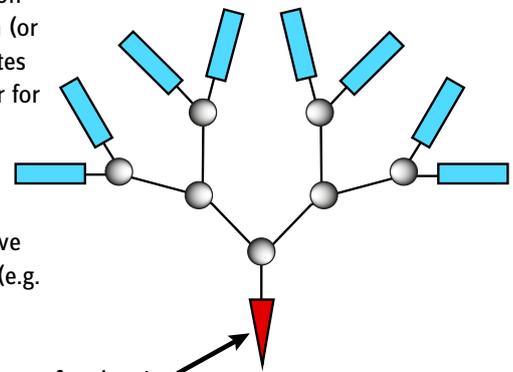

- I. Weigh out 1 eq. of Fmoc-hydrazone-pyruvyl-amino methylpolystyrene resin in a flask.
- II. Swell the resin in DMF using 10 mL of solvent per gram of resin.
- III. Remove solvent by filtration and deprotect Fmoc group by adding 10 mL of 20% (v/v) piperidine in DMF per gram of resin and agitate for 2 min [an alternative deprotection cocktail is 1% DBU/ 1% Pip (v/v) in DMF].
- IV. Repeat step III with 8 min reaction time.
- V. Remove the piperidine solution by filtration and wash 5 times with DMF.
- VI. Weigh out 3 eq. (relative to resin loading) of carboxylic acid in a container and dissolve in minimal volume of DMF.
- VII. Add 1 eq. of HCTU (relative to the carboxylic acid) and 2 eq. of DIEA to the vessel with the acid solution, and mix for 8 min.
- VIII. Add the mixture to the swollen resin and shake it for 20 h at 20 °C to 25 °C.
- IX. Remove solution by filtration and wash the resin 3 times with DMF.
- X. Perform a Kaiser test. In the case of positive test (blue or violet color) repeat from step VI.

Lysine Dendrons - easily accessible via Hydrazone Resin

Lysine dendrons with a hydrazide functional group at the focal point/C-terminus can undergo chemoselective conjugation with synthetic or natural polymers or molecules bearing aldehyde groups (in peptides for example by oxidation of N-terminal Ser or Thr residues). The conjugation can be performed with (or without) subsequent reduction of the hydrazone bond by NaBH₄. Conjugates then can for example be applied for the design of gene delivery systems or for modifying the surface properties of polymers.

DOTA-functionalized dendrons conjugated to peptide or polymer carrier molecules facilitate delivery of paramagnetic ions (Gd³⁺; Mn²⁺) or radioactive isotopes. Applications include the targeted delivery of MR contrast agents (e.g. Gd³⁺) and radio immunotherapy.

The triphenylphosphonium (TPP)-bearing dendron was designed for the targeted delivery of peptides, polymers and different drugs to mitochondria.

7. Scavenger Resins

In contrast to the solid supports previously discussed, the special resins in this chapter are not used to attach and modify molecules on solid support. Instead, these resins bear immobilized reagents that can be easily filtered off from the products after completion of the desired chemical transformation.

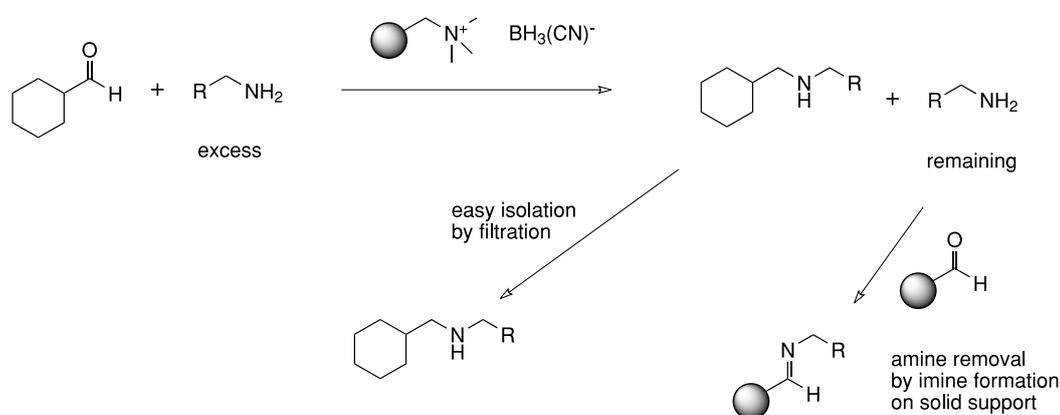

Scavenger resins are functionalized solid supports that are used for the rapid inactivation of reactive side products generated during solution phase chemistry. There is a wide variety of functional groups available on different resins that will react with various by-products to remove them from the reaction solution [80; 81].

Scavenger resins have become increasingly popular in solution phase combinatorial synthesis for active pharmaceutical ingredients [82; 83; 84; 85; 86; 87; 88; 89; 90; 91]. In comparison to other purification methods, scavenger resins have several advantages:

- ▶ Quick purification by easy and fast separation through filtration
- ▶ Can be used in excess to capture impurities more efficiently and faster
- ▶ Product stays in solution and can be subjected to further reactions without prior work-up
- ▶ Compatible with a wide variety of solvents
- ▶ Orthogonal purification principle that can be combined with other methods

Example: Reductive Amination and Excess Amine Removal

The following two-step procedure nicely demonstrates the application of solid-supported reagents and scavenger resins. Reductive amination often requires an excess of amine. The reducing borane reagent is immobilized by ionic interaction on a positively charged ammonium resin that can be easily filtered off once the reduction is completed. The excess of amine can then be removed by imine formation with an aldehyde resin and subsequent filtration.

Aldehyde resins have a significant advantage over other amine scavengers, such as isocyanate resins, as they are fully capable to distinguish between primary and secondary amines.

8. Standard Protocols for Peptide Synthesis

Protocol 9: Fmoc Deprotection (Fmoc Strategy)

- I. Swell the resin in DMF using 10 mL solvent per gram of resin.
- II. Discard excess liquid, and deprotect Fmoc group by adding 10 mL of 20% (v/v) piperidine in DMF per gram of resin, and agitating the resin for 10 min.
- III. Repeat step II with 5 min reaction time.
- IV. Discard the piperidine solution and wash 5 times with DMF.

Protocol 10: Boc Deprotection (Boc Strategy)

- I. Swell the resin in DCM using 10 mL solvent per gram of resin.
- II. Discard excess liquid and deprotect Boc group by adding 10 mL of 50% (v/v) TFA in DCM per gram of resin, and agitating for 5 min. Add 0.5% DTT when Cys, Met or Trp are present in the peptide.
- III. Repeat step II with 20 min reaction time.
- IV. Discard the TFA solution and wash 2 times with DCM and subsequently 2 times with IPA before neutralization.

Protocol 11: Neutralization after Boc Deprotection (Boc Strategy)

- I. Treat resin with 10 mL of 10% (v/v) TEA in DCM per gram resin for 10 min.
- II. Discard liquid and repeat step I.
- III. Wash the resin 3 times alternatingly with DCM and IPA each.

Protocol 12: Standard Amino Acid Coupling

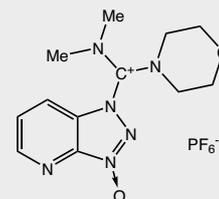

- I. Dissolve 2 eq. (relative to resin loading) of carboxylic acid, COMU and OxymaPure in a vessel with 10 mL of DMF per gram of resin.
- II. Add 1.0 eq. (relative to the amino acid) of DIEA to the vessel with the amino-acid solution and mix.
- III. Add the reaction solution to the swollen resin and shake the solution for 1 h at room temperature.
- IV. Remove solution by filtration and wash the resin 5 times with DMF.

Protocol 13: Difficult Amino Acid Coupling

Numerous protocols have been published for achieving good yields while coupling sterically hindered amino acids, such as Aib or other difficult carboxylic acids using reagents like HATU and/or HOAt. These reagents recently have been classified as explosives and hence cannot be used anymore by the peptide community. Modern substitutes are:

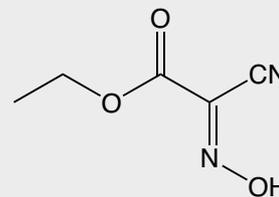

Substitute for HATU:

HDMA	RL-2170		
1-[(Dimethylamino)(morpholino)methylene]-1H-[1,2,3]triazolo[4,5-b]pyridine-1-ium 3-oxide hexafluorophosphate	RL-2170.0025	25 g	95,00
	RL-2170.0100	100 g	250,00
	RL-2170.0500	500 g	960,00
	RL-2170.1000	1 kg	1600,00

Substitute for HOAt:

OxymaPure	RL-1180		
Ethyl cyano(hydroxyimino)acetate, Ethyl cyanoglyoxylate-2-oxime	RL-1180.0100	100 g	75,00
	RL-1180.0500	500 g	200,00
	RL-1180.1000	1 kg	350,00

- I. Dissolve 2 eq. (relative to resin loading) of carboxylic acid, HDMA and OxymaPure in a vessel with 10 mL of DMF per gram of resin.
- II. Add 1.0 eq. (relative to the amino acid) of DIPEA to the vessel with the amino-acid solution and mix.
- III. Add the reaction solution to the swollen resin and shake the solution for 3 h at room temperature.
- IV. Remove solution by filtration and wash the resin 5 times with DMF.

Protocol 14: TFA Peptide Cleavage (Fmoc Strategy), high Concentration

- I. Add 20 mL of a TFA, water and TIPS mixture (95/2.5/2.5; v:v:v) to the dry resin and react for 2h.
- II. Separate cleavage cocktail from resin *via* filtration.
- III. Reduce volume of cleavage cocktail to approximately 10% of original volume.
- IV. Add 10 volumes of ice-cold diethyl ether (relative to remaining volume of cleavage cocktail) to precipitate peptide.
- V. Decant diethyl ether or filter off precipitate.
- VI. Wash 2 times with diethyl ether and dry peptide.

Protocol 15: Dilute TFA Peptide Cleavage (Fmoc Strategy)

Fully side chain protected peptides will be generated with highly acid-sensitive resins like 2-chlorotrityl resin, trityl-TentaGel or Sieber resins. Due to the high acid sensitivity of the peptide-resin bond and the hydrophobic nature of the cleaved, fully protected peptide, careful prior experimentation is necessary, and appropriate minor modifications of the protocol given below may be required.

- I. Swell the resin in DCM using 10 mL solvent per gram of resin and discard excess of liquid.
- II. Add 10 mL of a 1% TFA and 1% EDT in DCM, seal the container and shake for 2 min.
- III. Filter solution by applying gravity or nitrogen pressure (no vacuum!) into a flask containing 10% pyridine in MeOH (v/v 2 mL per 10 mL cleavage solution).
- IV. Repeat from step II 10 times.
- V. Wash with 3 x 30 mL DCM, 3 x 30 mL MeOH, 2 x 30 mL DCM, and 3 x 30 mL MeOH (per gram resin). Check filtrates by TLC or HPLC.
- VI. Combine filtrates and reduce volume to approximately 5% to 10% of original volume.
- VII. Add approximately double volume of water and cool the mixture with ice, in order to precipitate peptide.
- VIII. Filtrate precipitate and wash 3 times with water.

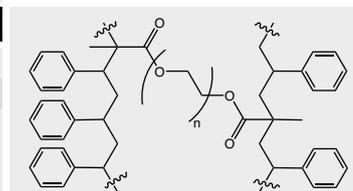

Protocol 16: Low-High HF Peptide Cleavage (Boc Strategy)

- I. A solution of DMS/*p*-cresol (65:10; v/v) (*p*-thiocresol if Trp(For) is present) is added to the reactor with the resin.
- II. Distill HF into the reactor until the solution reaches a HF/DMS/*p*-cresol ratio of 25:65:10 (v/v/v) with 10 mL solution per gram resin.
- III. Agitate for 2 h at 0-5 °C.
- IV. Evaporate HF and DMS under reduced pressure.
- V. Remove resin from reactor and wash with DCM.
- VI. Return resin to reactor with *p*-cresol.
- VII. Perform high HF cleavage for 1 h at 0-5 °C in a mixture of HF/*p*-cresol of 9:1 (v/v).
- VIII. Remove HF under reduced pressure.
- IX. Suspend the cleaved peptide and resin in diethyl ether and wash thoroughly with diethyl ether.
- X. Remove ether by drying.
- XI. Dissolve peptide in 50% aqueous acetic acid, filter off resin and dilute peptide solution with water.
- XII. Recover peptide by lyophilization or use solution directly for HPLC purification.

DESCRIPTION

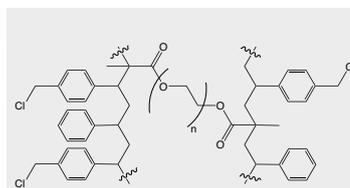

Labile to basic and nucleophilic conditions. Used for convenient preparation of protected fragments, cyclic peptides, and alternative C-terminal groups. Oxime resin is a synthesis resin compatible with Boc chemistry. Substrates can be cleaved from this resin under basic conditions, which leave the side chain and N-terminal protecting groups in place, making this resin very useful for preparing protected fragments that can be used in the segment condensation synthesis of larger substrates. This resin is also useful for preparing structural analogues which differ only at the C-terminus. By using different alkyl amines to displace the substrate from the resin, a series of N-alkylamides of the same substrate can be prepared. Likewise, using DBU and different alcohols a variety of esters can be prepared. Using acetate salts of amino acid esters produces a series of peptide analogues that differ only in the C-terminal amino acid. Although this resin is compatible with Boc chemistry, the oxime ester linkage is susceptible to TFA. Therefore, the Boc group is removed with 25% TFA in DCM during synthesis and end-capping is performed after each coupling to block any active sites on the resin that may have been exposed.

DESCRIPTION Due to its high loading this resin is particularly useful for the synthesis of protected peptide acid fragments. TentaGel® resins consist of low cross-linked polystyrene on which poly(ethylene glycol) with a molecular weight of 1500 Da to 2000 Da is grafted. The PEG spacer is attached to the polymer matrix via an ether bond, which shows high stability towards acid treatment and minimizes PEG leaching. The properties of TentaGel® resins are dominated by PEG, which solubilizes both hydrophobic and hydrophilic compounds. TentaGel® resins are pressure stable and can be used in batch processes as well as under continuous flow conditions.

2-Chlorotrityl Chloride Resin

A Versatile Resin Available in Ton Lots!

Convergent peptide synthesis

Fmoc/tBu protected peptides, synthesized on a 2-chlorotrityl resin, have been quantitatively esterified by treatment with 2-chlorotrityl chloride and diisopropylethylamine. The obtained peptide chlorotrityl esters were deprotected at the N-function and subsequently condensed in soln. to larger peptides. The chlorotrityl ester function of the obtained products could be selectively removed by treatment with AcOH.

Literature:

Athanassopoulos, Panagiotis; Barlos, Kleomenis; Gatos, Dimitrios; Hatzi, Olga; Tzavara, Chrysoula; *Tetrahedron Letters* 1995; **36(31)**: 5645-8.

Solid phase synthesis of (Leu15)-gastrin I and unsulfated cholecystokinin octapeptide.

The carboxyl terminal dipeptide amide, Fmoc-Asp-Phe-NH₂ of gastrin and cholecystokinin (CCK) has been attached in high yield through its free side chain carboxyl group to the acid-labile 2-chlorotrityl resin. The obtained peptide resin ester has been applied in the solid phase synthesis of partially protected (Leu15)-gastrin I utilizing Fmoc amino acids. Quantitative cleavage of this peptide from resin, with the tBu type side chain protection intact is achieved using mixtures of acetic acid/trifluoroethanol/dichloromethane. Under the same conditions, complete detritylation of the tyrosine phenoxy function occurs simultaneously. Thus, the solid-phase synthesis of peptides selectively deprotected at the side chain of tyrosine is rendered possible by the use of 2-chlorotrityl resin and Fmoc-Tyr(Trt)-OH. The efficiency of this approach has been proved by the subsequent high-yield synthesis of 3 model peptides and CCK octapeptide.

Literature:

Barlos, Kleomenis; Gatos, Dimitrios; Kapolos, Stavros; Poulos, Constantine; Schafer, Wolfram; Yao, Wenqing. *International Journal of Peptide & Protein Research* 1991; **38(6)**: 555-61.

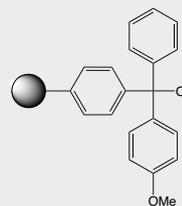

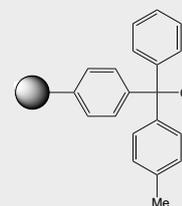

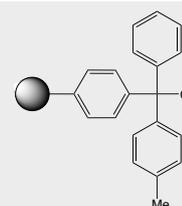

Anchoring of Fmoc-amino acids and peptide cleavage

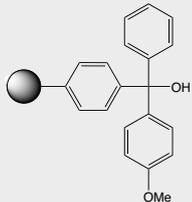

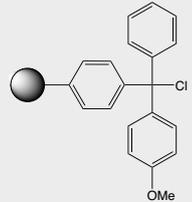

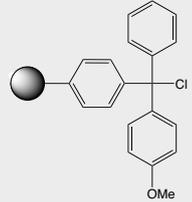

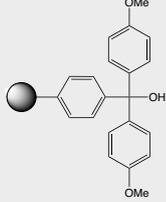

The esterification of 2-chlorotrityl chloride resin with Fmoc-amino acids in the presence of DIPEA is studied under various conditions. High esterification yields are obtained using 0.6 equiv. Fmoc-amino acid/mmol resin in DCM or ClCH₂CH₂Cl in 25 min at room temp. The reaction proceeds without by-product formation even in the case of Fmoc-Asn-OH and Fmoc-Gln-OH. The quantitative and easy cleavage of amino acids and peptides from 2-chlorotrityl resin using AcOH/TFA/DCM mixtures is accomplished within 15-60 min at room temperature while tBu type protecting groups remain unaffected. Under these exceptionally mild conditions, 2-chlorotrityl cations generated during the cleavage of amino acids and peptides from resin do not attack the nucleophilic side chains of tryptophan, methionine, and tyrosine.

Literature:

Barlos, Kleomenis; Chatzi, Olga; Gatos, Dimitrios; Stavropoulos, George. *International Journal of Peptide & Protein Research* 1991; **37(6)**: 513-20.

SYNONYMS	3-methoxy-4-(hydroxymethyl)phenoxyacetyl-TentaGel S resin			
DESCRIPTION	Peptides and other esters can be cleaved with 1-5% TFA in DCM. This property makes it very useful for a high number of applications. TentaGel® resins consist of low cross-linked polystyrene on which poly(ethylene glycol) with a molecular weight of 3000 Da is grafted. The PEG spacer is attached to the polymer matrix via an ether bond, which shows high stability towards acid treatment and minimizes PEG leaching. The properties of TentaGel® resins are dominated by PEG, which solubilizes both hydrophobic and hydrophilic compounds. TentaGel® resins are pressure stable and can be used in batch processes as well as under continuous flow conditions.

DESCRIPTION Due to modifications of the polystyrene backbone TentaGel XV shows extended swelling properties providing a large reaction volume. It is a superior resin for synthesizing difficult sequences, aggregating peptides, mini proteins, and PNAs in high purity and excellent yields.

DESCRIPTION Fmoc-Sieber amide resin is an acid-labile carrier for solid phase synthesis of peptide amides. Cleavage can be achieved with only 1% TFA in DCM making them an ideal carrier for the synthesis of protected peptide fragments in fragment condensation strategies for the synthesis of long peptides. It has also been used in organic synthesis of acid-sensitive compounds, for targeted synthesis of primary amines and N-alkylated secondary carboxyamides.

DESCRIPTION This resin is an ideal support for aldehyde immobilization via acetal formation. TentaGel® resins consist of low cross-linked polystyrene on which poly(ethylene glycol) with a molecular weight of 1500 Da to 2000 Da is grafted. The PEG spacer is attached to the polymer matrix via an ether bond, which shows high stability towards acid treatment and minimizes PEG leaching. The properties of TentaGel® resins are dominated by PEG, which solubilizes both hydrophobic and hydrophilic compounds. TentaGel® resins are pressure stable and can be used in batch processes as well as under continuous flow conditions.				

Stability of Benzyl-type Protecting Groups and Linkers

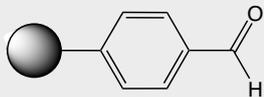

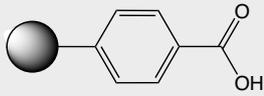

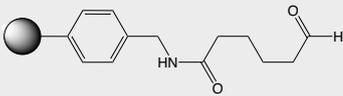

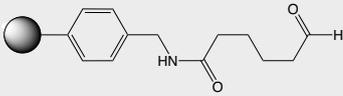

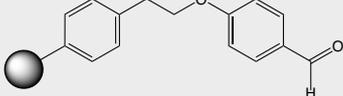

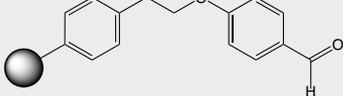

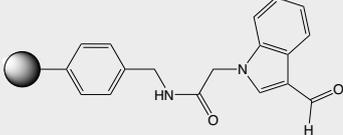

Benzyl, Benzhydryl and Trityl moieties are frequently used as protecting groups, as linkers for solidphase synthesis, or as important structural elements of both categories. The reason for this popularity is that the bond between benzylic carbons and neighboring moieties can be cleaved under relatively mild conditions. This is a result of the high degree of stabilization of the carbenium ion on the benzylic position that is formed upon acidic cleavage by delocalization of the positive charge. The degree of delocalization is higher and thus the stabilization stronger the more phenyl rings are attached to the benzylic position.

The stability of benzyl-type protecting groups and linkers can be fine-tuned by the incorporation of substituents on the phenyl rings that modify the electron density on the benzylic position, or change the degree of overlap of the π -orbitals of several phenyl rings. In the former category, methyl and methoxy groups are the most frequently used substituents to further stabilize benzylic carbocations, thereby allowing for even milder cleavage conditions. In the latter category, chlorine is the most common substituent. In trityl groups, the large atomic radius of chlorine results in a less planar conformation of the three phenyl rings, which in turn leads to a reduction of π -orbital overlap. The degree of delocalization of a positive charge on the benzylic position is thereby decreased, which means that the protecting group or linker in question is more difficult to cleave and thus more stable. Hence, the following row of stability can be defined:

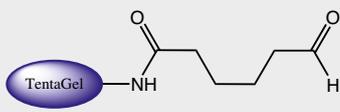

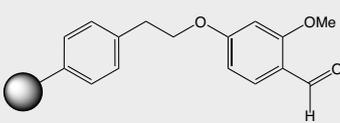

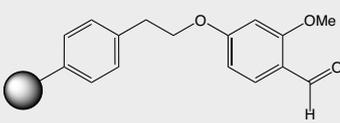

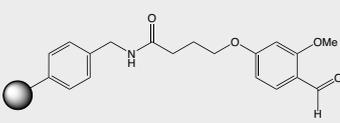

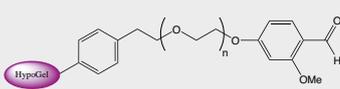

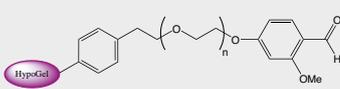

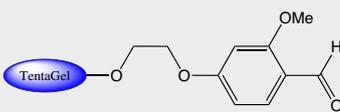

2-chlorotrityl > trityl > 4-methyltrityl > 4-methoxytrityl > 4,4'-dimethoxytrityl

DESCRIPTION Due to modifications of the polystyrene backbone TentaGel XV shows extended swelling properties providing a large reaction volume. It is a superior resin for synthesizing difficult sequences, aggregating peptides, mini proteins, and PNAs in high purity and excellent yields.

Custom Synthesis of Poly(amino acids) from Arg, Glu, Lys, Orn

Poly(amino acids) e.g. from **Arg, Glu, Orn** and **Lys** show the same pallet of diversity as PEGs and PSR enriched by the capability to functionalize the side chain. They gain increasing interest in polymer therapeutics and become a superior alternative as their biodegradability overcomes the limitation of PEG in this aspect. Their inherent side chain functionally expands the field of polymer therapeutics to small molecules and enables in a smart way combination therapy.

Please provide the following information:

1. Nature of polymer, chain length or molecular weight
2. Random or block-copolymer, functionality of side residues
3. Functionality on head
4. Functionality on tail (pay attention whether it is compatible with the other terminus!)
5. Quantity (grams to kg) and standard custom synthesis or GMP production

Please contact us to define the polymer of your choice.

PAM5795.0001	1 g	90,00
PAM5795.0005	5 g	340,00

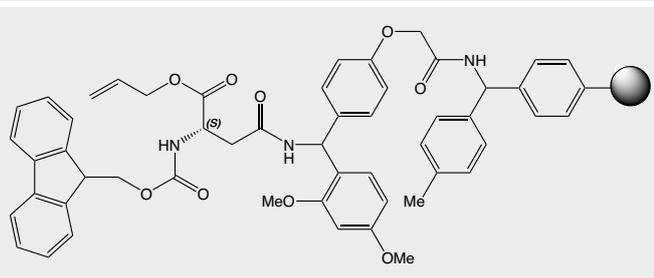

DESCRIPTION This resin can be used for the synthesis of peptide thioesters. After removal of Trt by TFA/DCM the first protected amino acid is loaded with standard protocol, followed by complete peptide synthesis. After completion the peptide thioester resin is treated with HF resulting in the deprotected peptide thioester, which can be used for chemical ligation strategies.

Solid phase peptide synthesis has been invented by using Merrifield resins, i.e. substituted methylpolystyrene. Amino acids have been protected at their α -amino function with Boc combined with orthogonal protection (Bzl and others) of the functional side groups. For final cleavage of the peptide, a strong acid like HF is required. Although this methodology produced highly pure peptides, the use is limited today due to the hazardous nature of HF. It almost has completely been substituted by the Fmoc/tBu approach.

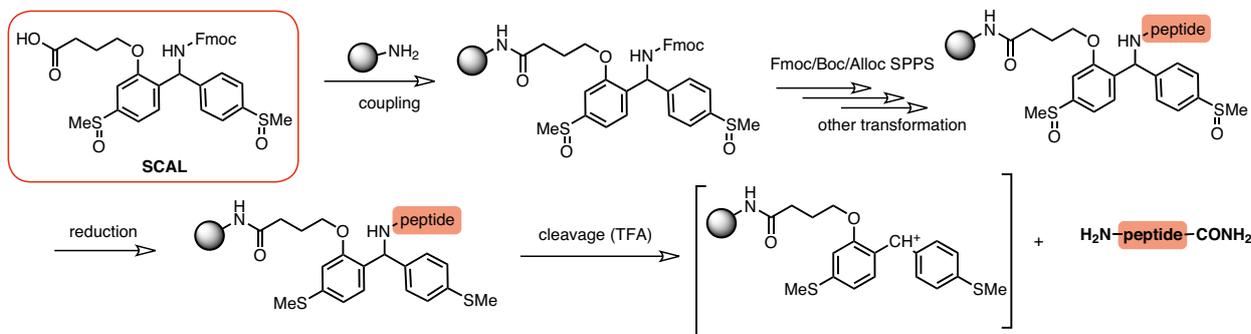

On demand we supply all L- and D-amino acids loaded onto Boc/Bzl compatible resins, like preloaded Merrifield and PAM resins.

Please inquire with type of amino acid, side protection, desired specifications and quantity.

Prices are in EUR, net, exw Germany

New: Safety Catch Acid-Labile Linker (SCAL)

Superior Chemical Stability & Permits Various Orthogonal Solid Phase Approaches

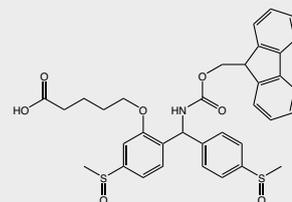

SCAL-Linker

RL-2260

5-(2-(((9H-fluoren-9-yl)methoxy)carbonylamino)(4-(methylsulfinyl)phenyl)methyl)-5-(methylsulfinyl)phenoxy)pentanoic acid

FORMULA $C_{35}H_{35}NO_7S_2$
MOL. WEIGHT 645,78 g/mol

RL-2260.0250	250 mg	250,00
RL-2260.0001	1 g	625,00
RL-2260.0005	5 g	2450,00

SYNONYMS Safety-Catch-Acid-Sensitive Linker, 5-(2-((Fmoc-amino)(4-(methylsulfinyl)phenyl)methyl)-5-(methylsulfinyl)phenoxy)pentanoic acid, Fmoc-amino-di(methylsulfinyl)benzhydryl linker

Stable to

- ✓ bases (aq. 0.5% NaOH, DBU in chloroform, 20-50% piperidine in DMF)
- ✓ acids (25-55% TFA/DCM, neat TFA 2h, HF at 0°C for 2h)
- ✓ Alloc/OAll deprotecting procedures
- ✓ hydrostannolysis (Bu_3SnH , $Pd(OAc)_2$, PPh_3 in AcOH and DCM)

When attached to a water compatible support like sepharose, the linker allows complete solid-phase chemical ligation after removing AcM protecting group from cysteine using $Hg(II)(AcO)_2$ in aq. acetic acid (pH 4).

Final detachment occurs by reduction of sulfoxides followed by acidolysis providing C-terminal peptide amides [92]:

- ★ One-step procedures: $NH_4I/TFA/DMS$ (0°C to rt over 1h) or $1M SiCl_4(TFA/thioanisole/cresol/ethandithiol)$ (0°C, 2h)
- ★ Two-step procedures: a) reductive activation
($TMSiCl/PPH_3$ in DCM or THF, 20% $(EtO)_2P(S)SH/DMPU$, 0,1% HBr in AcOH (rt, 2h)
- b) acidolytic cleavage by a variety of TFA/scavengers mixes
(TFA/water, 95:5; TFA/DCM/water/ Bu_3SiH , 85:10:2.5:2.5; TFA/m-cresole; TFA/DCM, 1:1)

Boc Chemistry without the necessity to use HF!

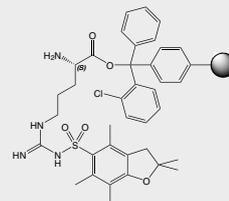

Try the New SCAL Linker and enjoy Production of Peptides in High Yield & High Purity!

DESCRIPTION	<p>The Clt (2-chlorotrityl) protecting group is more stable than the commonly used Trt group and is best deprotected by oxidative methods with iodine resulting in a simultaneous disulfide bridge formation. It is therefore best used in the synthesis of cyclic peptides with several disulfide bridges in particular for the synthesis of the second S-S bridge.</p> <p><u>Literature:</u> Aletras A., Barlos K. et al; <i>Int. J. Pept. Protein Res.</i> 1995; 45(5): 488-496. Barlos K. et al; <i>Int. J. Pept. Protein Res.</i> 1991; 38(6): 555-561. Sarah L.M. et al, in „Fmoc Solid Phase Synthesis. A practical approach“, Ed.: Chan W.C.; White P.D. Oxford University Press 2000, page 177.</p>

DESCRIPTION	<p>The Mmt function can be cleaved selectively in the presence of t-butyl type protecting groups and of 4-methyl benzhydryl resin (see BR-1180), Wang resin or Rink amide MBHA resin (Product code BR-1300, BR-1305, BR-1360, BR-1365, and BR-1366). The liberated thiol function then selectively reacts with various compounds, such as haloacyl or haloalkyl PEG derivatives or can be oxidized, in order to form disulfide bridges. Cleavage conditions for Cys(Mmt): 1 g of resin-bound peptide is washed 4 times with dichloromethane. Then 10 ml of an 1.1 % TFA mixture of dichloromethane/triethylsilane (97:3) are added and the mixture is shaken for 10 min at RT and filtered. The cleavage is repeated 1-3 times until no more Mmt can be detected. The Mmt detection is easily performed by applying a spot of the cleavage mixture on a TLC plate and exposes it a few seconds to gaseous HCl coming from conc. HCl. The presence of the Mmt-cation is visualized immediately by the orange coloration of the spot. The highly acid labile S-Mmt group is preferred over the StBu group for the SPS of S-palmitoyl transmembrane peptides since the latter give rise to quantitative desulphurization during resin deprotection.</p> <p><u>Literature:</u> K. Barlos et al. in "Peptides 1992, Proc. 22nd European Peptide Symposium", C.H. Schneider and A. N. Eberle (Eds), ESCOM, Leiden 1993. K. Barlos, et al.; <i>Int. J. Peptide Protein Res.</i> 1996; 47: 148. D. T. S. Rijkers, et al.; <i>Tetrahedron Letters</i> 2005; 46: 3341-3345.</p>

DESCRIPTION The Clt (2-chlorotrityl) protecting group is more stable than the commonly used Trt group and is being deprotected with 95%TFA in dichloromethane. The main application is in peptide synthesis, whenever certain treatments and modifications of the peptide are being applied, where the standard His(Trt) protection is too labile.

DESCRIPTION	<p>Natural Mimosine extracted from <i>Leucaena leucocephala</i> de Wit is a sustainable starting material for development of drugs or cosmetics. Mimosine inhibits tyrosinase, cyclooxygenase and lipoxygenase thus cosmetic application for whitening is one of the big interests. Hydroxy keton derivatives (like mimosine) induce apoptosis and have potential as anti-tumor agents. Mim exhibits no significant cytotoxicity nor acute dermal toxicity. This building block opens the field to use mimosine in peptides or organic molecules as key fragment and equip the drug molecule with the mimosine specific properties.</p> <p><u>Literature:</u> Nokihara, K, <i>et al.</i>, Preparative scale isolation, purification and derivatization of mimosine, a non-proteinogenic amino acid; <i>Amino Acids</i> 2011; Published online 13 Oct 2011. DOI 10.1007/s00726-011-1104-y. Nokihara, K, <i>et al.</i>, A Non-proteinogenic Amino Acid, Mimosine and Mimosyl Peptides for Cosmeceutical Ingredients; <i>Peptide Science</i> 2010, <i>The Japanese Peptide Society</i> 2011; 282.</p>

<p>DESCRIPTION The Clt (2-chlorotrityl) protecting group can selectively be removed by treatment with 1% TFA in dichloromethane and silane scavenger. The partially deprotected amino acid can be used for further derivatization, like phosphorylation, sulfonation, PEGylation, or conjugation with glycol building blocks or dyes.</p> <p>Literature: Aletras A., Barlos K. et al; <i>Int. 9.2.3. Preloaded Trityl-TentaGel® Resins for the Synthesis of Protected Peptides

TentaGel® resins consist of low cross-linked polystyrene on which poly(ethylene glycol) with a molecular weight of 3000 Da is grafted. The PEG spacer is attached to the polymer matrix via an ether bond, which shows high stability towards acid treatment and minimizes PEG leaching. The properties of TentaGel® resins are dominated by PEG, which solubilizes both hydrophobic and hydrophilic compounds. TentaGel® resins are pressure stable and can be used in batch processes as well as under continuous flow conditions.

9.2.4. Preloaded AC-TentaGel® Resins for the Synthesis of Protected Peptides

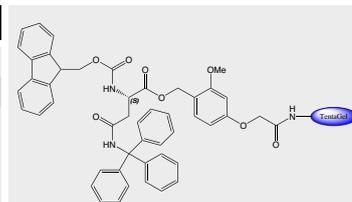

TentaGel® resins consist of low cross-linked polystyrene on which poly(ethylene glycol) with a molecular weight of 3000 Da is grafted. The PEG spacer is attached to the polymer matrix via an ether bond, which shows high stability towards acid treatment and minimizes PEG leaching. The properties of TentaGel® resins are dominated by PEG, which solubilizes both hydrophobic and hydrophilic compounds. TentaGel® resins are pressure stable and can be used in batch processes as well as under continuous flow conditions.

Peptides and other esters can be cleaved with 1-5% TFA in DCM. This property makes it very useful for the synthesis of protected peptide fragments and a high number of other applications.

9.2.5. Hydrazone Resins for the Synthesis of Peptide Thio Esters and Native Chemical Ligation

This novel hydrazine resin, derived from pyruvic acid, provides a new and convenient method for the synthesis of peptide hydrazides, which can be applied during ligation technique. It was shown that the hydrazone linker is completely stable in the course of standard Fmoc SPPS. Moreover, it can tolerate a treatment with 5 % TFA/DCM thus permitting selective removal of Mtt or related acid-labile protecting groups. Subsequent application of cleavage cocktails containing neat TFA permits to obtain the desired peptides in good yields and premium purity [76].

9.2.6. SEA Resins for the Synthesis of Peptide Thio Esters and Native Chemical Ligation

New resin for the synthesis of long peptides and mini-proteins. An elegant method of forming peptide thioesters as fragments for the synthesis of mini-proteins with natural peptide ligation techniques (NPL) [74; 75; 76; 77; 78]

9.2.8. Preloaded Wang-TentaGel® Resins

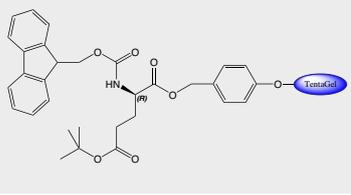

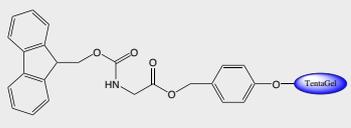

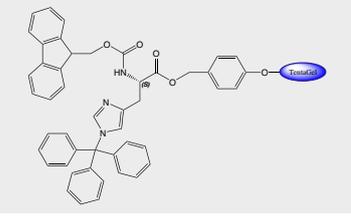

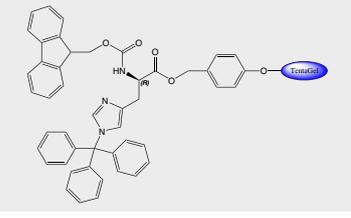

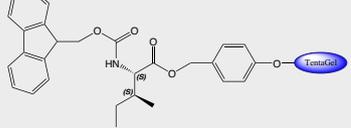

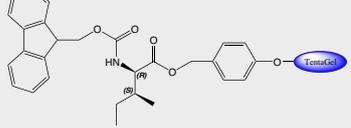

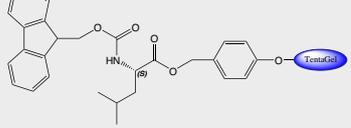

TentaGel® resins consist of low cross-linked polystyrene on which poly(ethylene glycol) with a molecular weight of 3000 Da is grafted. The PEG spacer is attached to the polymer matrix via an ether bond, which shows high stability towards acid treatment and minimizes PEG leaching. The properties of TentaGel® resins are dominated by PEG, which solubilizes both hydrophobic and hydrophilic compounds. TentaGel® resins are pressure stable and can be used in batch processes as well as under continuous flow conditions.

DESCRIPTION	<p>Aldehyde Resin, polystyrene resin functionalized with an aldehyde end group. It is a polymer bound equivalent of benzaldehyde, and is highly capable of scavenging excess amines from reaction media. This product has significant advantages over other scavengers of amines in that it's fully capable of distinguishing between primary and secondary amines. Isocyanate resin is equally proficient in sequestering either, so reactions that contain both moieties are dealt with more effectively with PS-Aldehyde.</p> <p><u>Literature:</u> Frechet J. M.; <i>J. Am. Chem. Soc.</i> 1971; 93: 492-496. Cacchi S.; <i>Synthesis</i> 1979; 64-66. Creswell M. W.; <i>Tetrahedron</i> 1998; 54: 3983-3998. Hodges J. C.; <i>Synlett</i> 1999; 1: 152-158. Ley S. V.; <i>J. DESCRIPTION Morpholine Resin, polystyrene resin functionalized with a morpholine end group. It is a polymer bound equivalent of N-methyl-morpholine (NMM) and is capable of all reactions associated with its non-bound counterpart. Morpholine Resin, PS, is a gel-type polystyrene resin functionalized with a morpholine end group. It is commonly utilized as an acid scavenger useful for sequestering acidic residues as they are generated during reactions. Simple filtration provides the desired products while acids remain bound to the polymer. Its widely applied during the acylation and sulfonylation of amines but is competent in all environments where acid is generated and needs removal.

DESCRIPTION Isocyanate Resin, polystyrene resin functionalized with an isocyanate end group. This reagent has shown proficiency in the scavenging of primary and secondary amine containing compounds. Driving reactions to completion by the addition of excess amine is a common trick to improve the outcome of synthetic routes. Isocyanate resins have been utilized in scavenging excess amines from reductive aminations, as well as amide coupling reactions. This highly capable reagent is also efficient in removing other nucleophiles from reaction media. Thiols, alcohols and some anilines are effectively scavenged. The high reactivity of this material does have its limitations in that nucleophilic solvents pose compatibility issues.

DESCRIPTION Triethylamine Resin, polystyrene resin functionalized with a trimethylamine end group. It is a polymer bound equivalent of trimethylamine and is capable of all reactions associated with its non-bound counterpart. It is commonly utilized as an acid scavenger useful for sequestering acidic residues as they are generated during reactions, allowing for one-pot synthesis of amides and sulfonamides from acyl/sulfonyl halides. Simple filtration provides the desired products, while acids and unreacted starting materials remain bound to the polymer. Use of excess Triethylamine Resin effectively liberates amines from their salts including salicylate, formate and acetate salts. The resin has been found very effective in removing both aliphatic and aromatic carboxylic acid impurities in bulk applications.

DESCRIPTION	<p>Sulfonyl Chloride Resin, polystyrene resin functionalized with a p-tosyl chloride end group. It is an incredibly capable scavenger of basic compounds such as primary, secondary or tertiary amines. Other nucleophilic reagents such as alcohols and hydrazines are sequestered efficiently, as are some organometallics. It is particularly useful in a unique "catch and release" protocol in which alcohols are effectively tosylated, yet remain on the resin scaffold. These activated polymer intermediates are then purified by simple washing and are then 'released' with secondary amines, generating their tertiary counterparts.</p>		<p>Literature: Huang W.; <i>Reactive Polymers (Engl.)</i> 1992; 1: 61. DESCRIPTION Sulfonic Acid Resin, polystyrene resin functionalized with a p-toluenesulfonic acid end group. It is a strong cation-exchange resin and is capable of scavenging heterocyclic bases in addition to primary, secondary and tertiary amines. MP-TsOH can also be utilized in many acid catalyzed reactions such as acetal and ketal formation. It is an excellent choice for the 'catch and release' purification of amines resulting from a variety of reactions including reductive aminations. This resin is also quite effective in solid-phase extraction (SPE) of amine bases in sample preparation of bio-analytes such as blood, urine, etc.

10. Abbreviations

BrAA:	Bromoacetic acid
°C:	degree Celsius
COMU:	1-[1-(Cyano-2-ethoxy-2-oxoethylideneaminoxy)-dimethylamino-morpholino]-uronium hexafluorophosphate
DBU:	1,8-Diazabicyclo[5.4.0]undec-7-ene
Dde:	N-[1-(4,4-dimethyl-2,6-dioxocyclohex-1-ylidene)ethyl]
DIAD:	Diisopropylazodicarboxylate
DIC:	Diisopropylcarbodiimide
DIEA:	Diisopropylethylamine
DMAP:	4-Dimethylaminopyridine
DMF:	Dimethylformamide
DPPA:	Diphenylphosphoric acid azide
DVB:	Divinylbenzene
Fmoc:	Fluorenylmethoxycarbonyl
h:	hour
HATU:	1-[Bis(dimethylamino)methylene]-1H-1,2,3-triazolo[4,5-b]pyridinium 3-oxid hexafluorophosphate
HFIP:	Hexafluoroisopropanol
HOAt:	1-Hydroxy-7-azabenzotriazol
MBHA:	4-Methylbenzhydramine
min:	minute
mL:	milliliter
NMP:	N-Methyl Pyrrolidon
NMR:	nuclear magnetic resonance
Ns:	o-nitrobenzenesulfonamide
NsCl:	o-nitrobenzenesulfonylchloride
Ph:	Phenyl
RT:	room temperature
SPPS:	solid phase peptide synthesis
TBTU:	O-(1-H-Benzotriazol-1-yl)-N,N,N',N'-tetramethyluroniumtetra-fluoroborat
TFA:	Trifluoroacetic acid
THF:	Tetrahydrofuran
TIPS:	Triisopropylsilane

13. Terms and Conditions of Sales

All orders placed by a buyer are accepted and all contracts are made subject to the terms which shall prevail and be effective notwithstanding any variations or additions contained in any order or other document submitted by the buyer. No modification of these terms shall be binding upon Iris Biotech GmbH unless made in writing by an authorised representative of Iris Biotech GmbH.

Placing of Orders

Every order made by the buyer shall be deemed an offer by the buyer to purchase products from Iris Biotech GmbH and will not be binding on Iris Biotech GmbH until a duly authorised representative of Iris Biotech GmbH has accepted the offer made by the buyer. Iris Biotech GmbH may accept orders from commercial, educational or government organisations, but not from private individuals and Iris Biotech GmbH reserves the right to insist on a written order and/or references from the buyer before proceeding.

There is no minimum order value. At the time of acceptance of an order Iris Biotech GmbH will either arrange prompt despatch from stock or the manufacture/acquisition of material to satisfy the order. In the event of the latter Iris Biotech GmbH will indicate an estimated delivery date. In addition to all its other rights Iris Biotech GmbH reserves the right to refuse the subsequent cancellation of the order if Iris Biotech GmbH expects to deliver the product on or prior to the estimated delivery date. Time shall not be of the essence in respect of delivery of the products. If Iris Biotech GmbH is unable to deliver any products by reason of any circumstances beyond its reasonable control („Force Majeure“) then the period for delivery shall be extended by the time lost due to such Force Majeure. Details of Force Majeure will be forwarded by Iris Biotech GmbH to the buyer as soon as reasonably practicable.

Prices, Quotations and Payments

Prices are subject to change. For the avoidance of doubt, the price advised by Iris Biotech GmbH at the time of the buyer placing the order shall supersede any previous price indications. The buyer must contact the local office of Iris Biotech GmbH before ordering if further information is required. Unless otherwise agreed by the buyer and Iris Biotech GmbH, the price shall be for delivery ex-works. In the event that the buyer requires delivery of the products otherwise than ex-works the buyer should contact the local office of Iris Biotech GmbH in order to detail its requirements. Iris Biotech GmbH shall, at its discretion, arrange the buyer's delivery requirements including, without limitation, transit insurance, the mode of transit (Iris Biotech GmbH reserves the right to vary the mode of transit if any regulations or other relevant considerations so require) and any special packaging requirements (including cylinders). For the avoidance of doubt all costs of delivery and packaging in accordance with the buyer's requests over and above that of delivery in standard packaging ex-works shall be for the buyer's account unless otherwise agreed by both parties. Incoterms 2010 shall apply. Any tax, duty or charge imposed by governmental authority or otherwise and any other applicable taxes, duties or charges shall be for the buyer's account. Iris Biotech GmbH may, on request and where possible, provide quotations for multiple packs or bulk quantities, and non-listed items. Irrespective of the type of request or means of response all quotations must be accepted by the buyer without condition and in writing before an order will be accepted by Iris Biotech GmbH. Unless agreed in writing on different terms, quotations are valid for 30 days from the date thereof. Payment terms are net 30 days from invoice date unless otherwise agreed in writing. Iris Biotech GmbH reserves the right to request advance payment at its discretion. For overseas transactions the buyer shall pay all the banking charges of Iris Biotech GmbH. The buyer shall not be entitled to withhold or set-off payment for the products for any reason whatsoever. Government/Corporate Visa and MasterCard (and other such credit cards) may be accepted on approved accounts for payment of the products. Personal credit cards are not acceptable. Failure to comply with the terms of payment of Iris Biotech GmbH shall constitute default without reminder. In these circumstances Iris Biotech GmbH may (without prejudice to any other of its rights under these terms) charge interest to accrue on a daily basis at the rate of 2% per month from the date upon which payment falls due to the actual date of payment (such interest shall be paid monthly). If the buyer shall fail to fulfil the payment terms in respect of any invoice of Iris Biotech GmbH Iris Biotech GmbH may demand payment of all outstanding balances from the buyer whether due or not and/or cancel all outstanding orders and/or decline to make further deliveries or provision of services except upon receipt of cash or satisfactory securities. Until payment by the buyer in full of the price and any other monies due to Iris Biotech GmbH in respect of all other products or services supplied or agreed to be supplied by Iris Biotech GmbH to the buyer (including but without limitation any costs of delivery) the property in the products shall remain vested in Iris Biotech GmbH.

Shipping, Packaging and Returns

The buyer shall inspect goods immediately on receipt and inform Iris Biotech GmbH of any shortage or damage within five days. Quality problems must be notified within ten days of receipt. Goods must not be returned without prior written authorisation of Iris Biotech GmbH. Iris Biotech GmbH shall at its sole discretion replace the defective products (or parts thereof) free of charge or refund the price (or proportionate price) to buyer. Opened or damaged containers cannot be returned by the buyer without the written prior agreement of Iris Biotech GmbH. In the case of agreed damaged containers which cannot be so returned, the buyer assumes responsibility for the safe disposal of such containers in accordance with all applicable laws.

Product Quality, Specifications and Technical Information

Products are analysed in the Quality Control laboratories of Iris Biotech GmbH's production partners by methods and procedures which Iris Biotech GmbH considers appropriate. In the event of any dispute concerning reported discrepancies arising from the buyer's analytical results, determined by the buyer's own analytical procedures, Iris Biotech GmbH reserves the right to rely on the results of own analytical methods of Iris Biotech GmbH. Certificates of Analysis or Certificates of Conformity are available at the discretion of Iris Biotech GmbH for bulk orders but not normally for prepack orders. Iris Biotech GmbH reserves the right to make a charge for such Certification. Specifications may change and reasonable variation from any value listed should not form the basis of a dispute. Any supply by Iris Biotech GmbH of bespoke or custom product for a buyer shall be to a specification agreed by both parties in writing. Technical information, provided orally, in writing, or by electronic means by or on behalf of Iris Biotech GmbH, including any descriptions, references, illustrations or diagrams in any Catalogue or brochure, is provided for guidance purposes only and is subject to change.

Safety

All chemicals should be handled only by competent, suitably trained persons, familiar with laboratory procedures and potential chemical hazards. The burden of safe use of the products of Iris Biotech GmbH vests in the buyer. The buyer assumes all responsibility for warning his employees, and any persons who might reasonably be expected to come into contact with the products, of all risks to person and property in any way connected with the products and for instructing them in their safe handling and use. The buyer also assumes the responsibility for the safe disposal of all products in accordance with all applicable laws.

Uses, Warranties and Liabilities

All products of Iris Biotech GmbH are intended for laboratory research purposes and unless otherwise stated on product labels, in the catalogue and product information sheet of Iris Biotech GmbH or in other literature furnished to the buyer, are not to be used for any other purposes, including but not limited to use as or as components in drugs for human or animal use, medical devices, cosmetics, food additives, household chemicals, agricultural or horticultural products or pesticides. Iris Biotech GmbH offers no warranty regarding the fitness of any product for a particular purpose and shall not be responsible for any loss or damage whatsoever arising therefrom. No warranty or representation is given by Iris Biotech GmbH that the products do not infringe any letters patent, trademarks, registered designs or other industrial rights. The buyer further warrants to Iris Biotech GmbH that any use of the products in the United States of America shall not result in the products becoming adulterated or misbranded within the meaning of the Federal Food, Drug and Cosmetic Act (or such equivalent legislation in force in the buyer's jurisdiction) and shall not be materials which may not, under sections 404, 505 or 512 of the Act, be introduced into interstate commerce. The buyer acknowledges that, since the products of Iris Biotech GmbH are intended for research purposes, they may not be on the Toxic Substances Control Act 1976 („TSCA“) inventory. The buyer warrants that it shall ensure that the products are approved for use under the TSCA (or such other equivalent legislation in force in the buyer's jurisdiction), if applicable. The buyer shall be responsible for complying with any legislation or regulations governing the use of the products and their importation into the country of destination (for the avoidance of doubt to include, without limitation, the TSCA and all its amendments, all EINECS, ELINCS and NONS regulations). If any licence or consent of any government or other authority shall be required for the acquisition, carriage or use of the products by the buyer the buyer shall obtain the same at its own expense and if necessary produce evidence of the same to Iris Biotech GmbH on demand. Failure to do so shall not entitle the buyer to withhold or delay payment. Any additional expenses or charges incurred by Iris Biotech GmbH resulting from such failure shall be for the buyer's account. Save for death or personal injury caused by negligence of Iris Biotech GmbH, sole obligation of Iris Biotech GmbH and buyer's exclusive remedy with respect to the products proved to the satisfaction of Iris Biotech GmbH to be defective or products incorrectly supplied shall be to accept the return of said products to Iris Biotech GmbH for refund of the actual purchase price paid by the buyer (or proportionate part thereof), or replacement of the defective product (or part thereof) with alternative product. Iris Biotech GmbH shall have no liability to the buyer under or arising directly or indirectly out of or otherwise in connection with the supply of products by Iris Biotech GmbH to the buyer and/or their re-sale or use by the buyer or for any product, process or services of the buyer which in any way comprises the product in contract tort (including negligence or breach of statutory duty) or otherwise for pure economic loss, loss of profit, business, reputation, depletion of brand, contracts, revenues or anticipated savings or for any special indirect or consequential damage or loss of any nature except as may otherwise be expressly provided for in these terms. All implied warranties, terms and representations in respect of the products (whether implied by statute or otherwise) are excluded to the fullest extent permitted by law. The buyer shall indemnify Iris Biotech GmbH for and against any and all losses, damages and expenses, including legal fees and other costs of defending any action, that Iris Biotech GmbH may sustain or incur as a result of any act or omission by the buyer, its officers, agents or employees, its successors or assignees, its customers or all other third parties, whether direct or indirect, in connection with the use of any product. For the avoidance of doubt and in the event that Iris Biotech GmbH supplies bespoke or custom product to the buyer's design or specification, this indemnity shall extend to include any claim by a third party that the manufacture of the product for the buyer or the use of the product by the buyer infringes the intellectual property rights of any third party.

General

Iris Biotech GmbH shall be entitled to assign or sub-contract all or any of its rights and obligations hereunder. The buyer shall not be entitled to assign, transfer, sub-contract or otherwise delegate any of its rights or obligations hereunder. Any delay or forbearance by Iris Biotech GmbH in exercising any right or remedy under these terms shall not constitute a waiver of such right or remedy. If any provision of these terms is held by any competent authority to be invalid or unenforceable in whole or in part the validity of the other provisions of these terms and the remainder of the provision in question shall not be affected. These terms shall be governed by German Law and the German Courts shall have exclusive jurisdiction for the hearing of any dispute between the parties save in relation to enforcement where the jurisdiction of the German Courts shall be non-exclusive.

Publications from Iris Biotech:

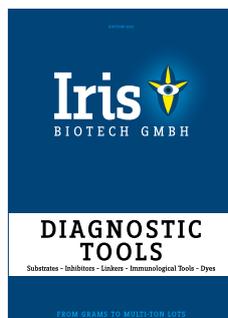

Brochure for **Click Chemistry** containing over 300 different Azido and Alkyne Compounds for drug discovery, drug delivery and diagnostics.

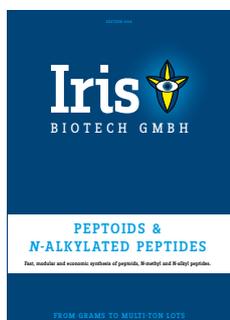

Disulfide bridges are an important structural element in many proteins and peptides. This brochure is a guideline how to plan and execute the **Synthesis of Cyclic Peptides** with one or several disulfide bridges.

Our **Comprehensive Drug Delivery Survey** contains the latest state-of-the-art collection of carriers for Polymer Therapeutics available today. More than 900 products from the areas PEGylation, poly (amino acids) and PEG-based multifunctional Dendrimers give the medicinal chemist all options to find the right delivery technology from small drug molecules up to large biopharmaceuticals.

Find in our brochure **Diagnostic Tools** plenty of substrates for reporter enzymes and drug interaction studies, metabolites, glucuronides and inhibitors, inducers, antibody conjugates and cross-linkers, natural products with biological and pharmacological activity, carbohydrates, dyes and fluorescent labels as Tools in Immunology, Diagnostic, Biochemistry and Molecular Biology.

Alkylation of peptides' amide nitrogens can overcome peptides' lability towards enzymatic degradation and its limited ability to cross biological barriers. Additionally, *N*-alkyl groups can also induce better receptor selectivity by increased rigidity and reduced conformational space. Check out tremendous new possibilities with **Peptoids & N-Alkylated Peptides** and find in this new brochure protocols, compounds and kits to produce them.

We are carrying out many Contract Manufacturing projects in the areas of our activities; our strong points are unusual derivatives with one or several chiral centres. Specific propriatry platforms give access to a wide variety of of unusual amino acid building blocks, polyamines and resins.
